- LIFE PRINCIPLES AND PRACTICE OF ENDOCRINE MEDICINE.** By WILLIAM NATHANIEL BERKELEY, Ph.D., M.D. Octavo of 368 pages, with 56 illustrations and 4 colored plates. Philadelphia and London, Lea and Febiger, 1926 Cloth, \$4.50

REDUCING FAT

The New York Times, February 24th, has an account of a conference in the Academy of Medicine on February 23rd on the subject of the prevailing fad of reducing weight. The article quoted Dr. Gregory, of the Psychopathic Department of Bellevue Hospital, as saying:

"Mental breakdowns from this fad are on the increase, 225 cases being traced to it last year. The reduction of weight was not the real factor on the breakdowns, but it was the final cause. Such individuals were of a pathological psychopathic type with a tendency to psychopathic disturbance which might have been overcome if the patient had not reduced her weight to the point where she became irritable and depressed. In all cases of reduction, when the individual is willing to resort to all sorts of means of reducing her weight, the starting point is a mental condition."

Dr. Russell M. Wilder, of the Mayo Clinic, was quoted: "The modern fad for reducing has been productive of more good than harm."

There seemed to be a considerable difference of opinion regarding the effects of reducing weights, and of the methods employed. The article said that a committee was appointed to investigate the question.

The weight of the body is largely dependent on a proper endocrine balance. With some the balance is struck when the body is appreciably fat, and with others, when it is lean. The balance may change, and the lean young man may become obese in his forties. If the endocrine balance is disturbed, the patient will be weakened, whether it is by too little or too much diet. An excellent example of this is the effect of insulin in either too little or too great dosage.

The endocrine balance is largely dependent on heredity, and so heredity plays a large part in fatness and leanness. Dr. C. B. Davenport, of the Eugenics Record Office, Cold Spring Harbor, discusses the subject of heredity and weight in a brief paper in the U. S. Public Health Reports for November 27, 1925. He had investigated the histories and measurements of several hundred children in Washington, D. C., and had come to the conclusion that heredity had a great effect on nutrition, and must be considered in judging the hygienic weight of a patient.

VALUE OF FREE SERVICES OF DOCTORS

The New York Sun, December 31st, quotes the directors of the proposed Physicians' Home that the doctors of New York City contribute sixteen million dollars worth of free medical services annually. Since there are only slightly less

than 10,000 doctors listed in Greater New York, according to the Physicians' Directory of the Medical Society of the State of New York, each physician contributes an average of sixteen hundred dollars worth of medical services each year.

The same authority estimates the money value of free medical services given by doctors of the United States outside of New York City at \$135,000,000 annually, and bases its estimate on an average contribution of \$821, or about one-half that of the average physician in New York City.

The estimation further includes the statement that the average doctor makes a free contribution of 40 per cent of the value of his services. If this is true, then the average annual income of doctors is \$4,000 in New York City, and \$2,000 in the rest of the country.

It is the popular conception that doctors are financially prosperous. Some amass wealth, some acquire fame, and a few are noted for their altruistic motives, but no one knows how much money the average doctor makes. However, his credit seems to be as good as that of the average lawyer, or school teacher, or engineer, or journalist.

ACCURACY IN WRITING

Reading a newspaper is largely a matter of getting quick impressions from rapid glances at emphatic words. Writers for the "tabloid" morning papers take a small idea and repeat it over and over in such a form that it gives an impression of profundity of thought and research, when it really is only surmise. The *Herald-Tribune* of April 5 comments on this kind of writing as follows:

"The cynicism of the editors of the *Macfad-dengraphic* about the mental capacities of their readers is appalling, the accuracy of their estimate is heartbreaking. These gentlemen hazarded the guess that, if they should label a picture 'an accurate composite photograph' their public would confuse accurate with actual, and take the word composite to be some technical and non-essential terms. They were right."

"Next they calculated that if they should describe a Life Story as 'authorized by Gerald Chapman' the same public would skip lightly to the conclusion that the verb authorize comes directly from the noun author, and believe Chapman to be the author of the series. They appear to be right again."

"So the circulation of the little pink fellow increases by leaps and bounds, and the will of the people is still widely reputed to be the will of God."

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

- APPLIED BIOCHEMISTRY** By WITHROW MORSE. Octavo of 938 pages with 257 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$7.00
- A TEXT-BOOK OF MEDICAL DIAGNOSIS** By JAMES M. ANDERS, M.D., Ph.D., LL.D., and L. NAPOLEON BOSTON, A.M., M.D. Third edition. Octavo of 1422 pages, with 555 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$12.00
- THORACIC SURGERY** The Surgical Treatment of Thoracic Disease. By HOWARD LILIENTHAL, M.D., F.A.C.S. Two Octavo volumes totaling 1924 pages, with 904 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$20.00
- MASSAGE AND THERAPEUTIC EXERCISE** By MARY McMILLAN. Second Edition. 12mo of 331 pages with 17 illustrations. Philadelphia and London, W B Saunders Company, 1925 Cloth \$2.50
- CHEMICAL PATHOLOGY** Being a Discussion of General Pathology from the Standpoint of the Chemical Processes Involved. By H. GIDEON WELLS, Ph.D., M.D. Fifth Edition. Octavo of 790 pages. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$8.50
- ABDOMINAL AND PELVIC SURGERY FOR PRACTITIONERS** By RUTHERFORD MORISON, Hon.M.A. and D.C.L., Hon. LL.D., M.B., F.R.C.S. 12mo of 212 pages, with illustrations. New York, Oxford University Press, 1925 Cloth, \$2.75 (Oxford Medical Publications)
- POST-MORTEM APPEARANCES** By JOAN M. ROSS, M.B., B.S. M.R.C.S., L.R.C.P. 12mo of 216 pages. New York, Oxford University Press, 1925 Cloth, \$2.50 (Oxford Medical Publications)
- SURGICAL CLINICS OF NORTH AMERICA** Volume 5 Number 5 October, 1925 (St. Louis Number) Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00, Paper, \$12.00
- MEDICAL HEREDITY** Distinguished Children of Physicians (United States to 1910) By WILLIAM BROWNING Ph.B., M.D. Octavo of 250 pages. Baltimore, The Norman, Remington Company 1925 Cloth, \$4.00
- LIGHT AND HEALTH** A Discussion of Light and Other Radiations in Relation to Life and to Health. By M. LUCKIESH and A. J. PACINI. Octavo of 302 pages, illustrated. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$5.00
- PUBLIC HEALTH LAW** A Manual of Law for Sanitarians. By JAMES A. TOBEY, M.S., LL.B. Octavo of 304 pages. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$4.50
- A MEDICAL FORMULARY** By E. QUIN THORNTON, M.D. 12th Edition revised. 16mo of 352 pages. Philadelphia and New York, Lea and Febiger 1925 Cloth \$2.50
- PRESCRIPTION NOTES** By ARTHUR L. TAUM. 16mo of 22 pages, with blank pages for selected prescriptions. Chicago University of Chicago Press, 1925 Cloth, \$1.25
- OUR PRESENT KNOWLEDGE OF HEREDITY** A Series of Lectures given at the Mayo Foundation and the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis), 1923-1924. 12mo of 250 pages illustrated. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$2.50
- LECTURES ON NUTRITION** A Series of Lectures given at the Mayo Foundation and the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis) 1924-1925. 12mo of 243 pages, illustrated. Philadelphia and London, W B Saunders Company, 1925 Cloth, \$2.50
- THE MEDICAL CLINICS OF NORTH AMERICA** Volume 9 Number 4 January, 1926. (Tulane University Number) Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00, Paper, \$12.00
- ABDOMINAL OPERATIONS** By SIR BERKELEY MOYNIHAN. 4th Edition, revised. Two octavo volumes totaling 1217 pages with 470 illustrations, 10 in colors. Philadelphia and London, W B Saunders Company, 1926. Cloth, \$20.00
- MODERN MEDICINE ITS THEORY AND PRACTICE**. In Original Contributions by American and Foreign Authors. Edited by SIR WILLIAM OSLER, Bart., M.D., F.R.S. Third Edition thoroughly revised. Re-edited by THOMAS McCRAE, M.D. assisted by ELMER H. FUNK, M.D. Volume 2. Octavo of 891 pages, illustrated. Philadelphia and New York, Tea and Febiger, 1925 Cloth, \$9.00
- BERGEY'S MANUAL OF DETERMINATIVE BACTERIOLOGY** A Key for the Identification of Organisms of the Class Schizomycetes. By DAVID H. BERGEY. Second Edition. Octavo of 462 pages. Baltimore, Williams and Wilkins Company, 1925 Cloth, \$5.50.
- MUSCULAR ACTIVITY** By ARCHIBALD VIVIAN HILL, M.A., Sc.D., F.R.S. Octavo of 115 pages, with illustrations. Baltimore, Williams and Wilkins Company 1926 Cloth, \$2.75
- LEAD POISONING**. By JOSEPH C. AUB, LAWRENCE T. FAIRHILL, A. S. MINOT, and PAUL REZNIKOFF. Octavo of 265 pages, with illustrations. Baltimore, Williams and Wilkins Company 1926. Cloth, \$4.00 (Medicine Monographs, Volume 7)
- LACTOBACILLUS ACIDOPHILUS** By NICHOLAS KOPELOFF. Ph.D. Octavo of 211 pages. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$5.00
- BIRTH CONTROL FACTS AND RESPONSIBILITIES** A Symposium Dealing with this Important Subject from a Number of Angles. Edited by ADOLPH MEYER, M.D. 12mo of 157 pages. Baltimore, Williams and Wilkins Company, 1925 Cloth, \$3.00
- THE PRINCIPLES AND PRACTICE OF ENDOCRINE MEDICINE**. By WILLIAM NATHANIEL BERKELEY, Ph.D., M.D. Octavo of 368 pages, with 56 illustrations and 4 colored plates. Philadelphia and London, Lea and Febiger, 1926. Cloth, \$4.50.

BOOK REVIEWS

THE ART OF MEDICAL TREATMENT With Reference Both to the Patient and to his Friends By FRANCIS W PALFREY, M.D. Octavo of 463 pages Philadelphia and London, W B Saunders Company, 1925 Cloth, \$4 50

We have here a long waited book on treatment. The subject is taken up in an orderly and decisive manner. Not only are drugs and physical treatments considered, but what is seldom seen in other books, what to tell the patient's family and friends is very thoroughly considered. The entire management of any one case is put down in one, two, three order, and can be read in a minimum amount of time.

Where drugs are mentioned definite dosages are given and hence the reader is put on a definite trail. It is needless to say that the treatment considered for each disease is the last word in medicine.

The mode of diet calculations is gone into deeply and as in most treatment books we have a diet for obesity.

At the back of the book drugs are considered under their own class head such as stimulants, astringents, etc. Their dosage and indications are noted.

And last but not least is a chapter devoted to the treatment of quacks and pseudo medical cults. This completes a very clearly and concisely written book on medical treatment.

KENNETH MACINNES

PSYCHOLOGICAL HEALING A Historical and Clinical Study by PIERRE JANET, Professor of Psychology, College of France. Translated from the French by Eden and Cedar Paul. Two volumes. The Macmillan Company, New York, 1925. Price per set, \$14 00

This work is a comprehensive textbook dealing with all phases of psychological healing. The author's wide personal experience has given him an ample supply of case histories on which to draw in order to exemplify his point. The subject matter is interesting and the style is readable. The scope of the work is indicated by its division into the following four parts, namely, (1) search for mental and moral action, (2) utilization of the patient's automatism, (3) psychological economics, and (4) psychological acquisitions.

FREDERIC DAMRAU

THE THERAPY OF PUERPERAL FEVER. By Privatdozent Dr ROBERT KOEHLER, formerly Assistant Gynecological Department Krankenhaus Wieden, Vienna, Austria. American edition prepared by HUGO EHRENFEST, M.D., F.A.C.S., Associate in Obstetrics, Washington University School of Medicine, twenty-seven illustrations. The C V Mosby Co, St. Louis, Mo., 1925. Price \$4 00

Koehler has reviewed the treatment of puerperal fever. Surgery except for drainage is condemned, and the utter futility of most therapeutic procedures shown. Non-specific protein therapy and chemotherapy are discussed in a frankly controversial manner, and illustrative cases and necropsies from the author's apparently wide experience are used in support of the points he makes. Blood transfusion, so popular here, is dismissed with brief notice.

In general, the author is pessimistic as to the value of all treatment, and shows that "convincingly good results" cannot be proved for any method of treatment so far tried. The illustrations are mostly temperature charts, and there is an extensive bibliography which is, however, rather weak on American names.

Ehrenfest has rendered a great service in the translation of this work, for the treasures of German literature are still inaccessible to a great many students.

C. A. G

MANSON'S TROPICAL DISEASES A Manual of the Diseases of Warm Climates Edited by PHILIP H. MANSON-BAHR, D.S.O., M.A., M.D., D.T.M., and H. CANTAB, F.R.C.P., Lond. Physician Hospital Tropical Diseases, London., Eighth Edition, Revised. 20 color plates, 7 half-tone, 387 figures, maps and charts. William Wood and Co, New York, 1925. Price, \$11 00

Since the publication of the seventh edition of this book, Sir Patrick Manson, the original author has died, and this well known and authoritative text on Tropical Diseases has been revised and remodelled "in order to bring it abreast of the latest developments in this branch of medicine" by Dr Manson Bahr.

This text is such a standard in its field and so well known internationally, that it is not necessary to speak in detail of the contents. The material presented is described in such a logical and pleasing literary form, that it makes very pleasant reading. With a few exceptions, the diseases included are mostly of infectious origin, and quite a number of them may be encountered in temperate climates. For this reason it is a volume in which any physician will find much that is interesting. The publishers are to be congratulated on the very neat, compact and beautifully illustrated volume they have turned out.

J. C. REGAN

SYNOPSIS OF MID WIFERY AND GYNECOLOGY By ALEC W. BOURNE, B.A., M.B., B.Ch. (Camb.), F.R.C.S. (Eng.) Third Edition, Revised and Enlarged, with numerous Diagrams. William Wood and Co., New York, 1925. Price \$4 50

Within a book of 434 pages is given a complete synopsis of obstetrics and gynecology. Numerous line drawings are scattered through the text. The author has treated his subject in a surprisingly complete manner, displaying a wide knowledge of his subject, and a painstaking arrangement of the subject matter. As a complete and quick reference to any subject in the domain of obstetrics and gynecology it will be appreciated by the busy practitioner. The book is exactly what its title suggests, a synopsis. It is a real one and should serve as a useful supplement to the ordinary text-book.

F. B. DOYLE

INTRAVENOUS THERAPY—ITS APPLICATION IN THE MODERN PRACTICE OF MEDICINE. By WALTER FOREST DUTTON, M.D., Visiting Physician to the Northwest Texas Hospital. 64 half-tones and line engravings, some in colors. Second revised and enlarged edition. F. A. Davis Company, Philadelphia, 1925. Price \$6 00

Our recent experiences with those important therapeutic agents such as insulin, pituitrin, parathyroid, etc., serve to emphasize the importance of the subcutaneous and intravenous route for medication. This second edition of Dutton has been revised and much new material added. The edition is freely illustrated, the methods and technique are made perfectly clear and the indications and contra-indications for all the procedures are fully discussed. The book is divided into two parts the first of which deals with the problem of general technique. Twelve chapters are devoted to this phase and here we have a complete consideration of the subject of blood transfusion as well as intravenous anesthesia, use of arsenical preparations and venesection. The second part is devoted to the general subject of medication in the different diseases.

The author has taken up a difficult subject and has made a good job of it.

H. M. FEINBLATT

RADIOGRAPHY A Manual of X-ray Technique, Interpretation and Therapy By CHARLES D ENFIELD, M.D., F.A.C.P., Roentgenologist, St. Anthony's Hospital, Louisville, Ky 194 Illustrations P Blakiston's Son & Co, Philadelphia, 1925

The author of this work has attempted to produce something that would be of assistance to the beginner in Roentgenology. It is designed chiefly as an elementary reference book for those who for various reasons are compelled to do some x-ray work in connection with other work in medicine.

There is in this work all the information necessary for equipping and operating a small laboratory suitable for doing x-ray work within certain limitations. The technique of various examinations is well illustrated and there are a number of reproductions of x-ray negatives to aid interpretation. We unhesitatingly recommend this book to that class for whom it was intended

J G W

DIE PROPHYLAXE DER GROSSEN SCHILDRÜSE GLEICHZEITIG EIN STÜCK VERGLEICHENDE KLIMATOLOGIE DER SCHWEIZ UND EIN LEITFADEN FÜR SYSTEMISCHE NATURWISSENSCHAFTLICHE FORSCHUNGEN Von Dr med. HEINRICH HUNZIKER, Arzt in Adliswil bei Zürich. Mit einem Beitrag von Dr med. Hans Eggenberger, Arzt in Herisau (Appensell) Gr 8°, 360 Seiten, mit einer farbigen Tafel, 9 Abbildungen und 155 Tabellen. Preis, Fr 12. Verlag Ernst Bircher, Aktiengesellschaft Bern und Leipzig, 1924

This book is a voluminous, painstaking and extensive survey of the subject which the author treats. As he states the work concerns the prophylaxis of goitre, exclusive of the surgical conditions of cystic goitre and the atypical tumor formations whether benign or malignant. He restricts himself to the condition of the so-called physiologic goitre enlargements which do not harm the patient nor cause any particular suffering. Cases of the latter belong to the realm of surgery and internal medicine.

He treats of the importance of Iodine in all forms of life whether plant or animal and also of the general problems relating to goitre and iodine. Parenchymatous enlargement of the thyroid is found with Iodine deficiency. In many communities this deficiency has been made up by adding small doses of Iodine to the cooking salt.

Climatic conditions relating to goitre were extensively studied leading up to the important problem of prophylaxis in all its ramifications. The result of an extensive study of the relation between climatic conditions and goitre in Swiss recruits is reported. Thus, the factors influencing atmospheric conditions such as heat, humidity, altitude, condensation and the like are discussed in detail and with reference to their influence on the occurrence of goitre.

It is difficult to distinguish the line of separation between the normal gland and goitre and hence the author has used the phrase, "Prophylaxis in the case of the enlarged thyroid gland," meaning thereby any simple enlargement from the mildest to the most extreme. A careful distinction is made between prophylaxis and treatment, mention being made that in America, iodine is given mostly for treatment and therefore larger doses are used than those recommended for prophylaxis. A chapter is devoted to the practical application of Hunziker's work.

Considerable space is devoted to a discussion of suitable and workable methods of measuring the enlarged thyroid. Careful, in fact elaborate measurements were made. The size of the gland was studied in its relation to the length of the body, the weight and intelligence of the individual. Iodine is shown to support the natural growth processes

Furthermore the author shows that iodine given in fractions of a milligram daily, acts not only as a prophylaxis for the large thyroid gland but is a simple remedy of the greatest importance for the improvement in general health. It was found that more iodine was required in the cases of girls with enlarged glands, than in boys.

The book is recommended to all those interested in the relations of iodine to the occurrence of simple goitre. Deficiency of iodine is indisputably established as the cause of this condition. Parts of the book seem needlessly long. It is recommended particularly to students of the goitre problem especially research students, in fact to all those interested in the larger aspect of public health with special reference to the eradication of simple goitre in any population where it occurs.

EMIL GOETSCH

PHYSICAL CHEMISTRY IN BIOLOGY AND MEDICINE. By J F McCLENDON, Ph.D., and GRACE MEDES, Ph.D. Octavo of 425 pages, illustrated. Philadelphia and London, W R. Saunders Company, 1925. Cloth, \$4.50

There are two parts to the book. Part I is Physico-Chemical, dealing with The Colloid Particle, Hydrogen Ions, etc., while Part II is Physiologic, treating of Thermodynamics in the Living Body, Ionic Equilibria in Blood, etc.

The discussion of a number of important subjects is inadequate, e.g., Hydrolysis and Ampholytes. The language is loose in places, and inaccuracies are not rare, e.g., the definition of polar compounds (p 315), the statement "In case one of the radicals of an electrolyte is weak and the other strong" (p 82), and the fifth method of determining the iso-electric point (p 185). Frequently odds and ends of observations are lumped together haphazardly, giving the impression of an abstract of the literature rather than of an introduction to the subject (e.g., pp 125-6). In discussing causes of stomach acidity, theories from Prout (1825) to date are given while the Donnan membrane theory is not even mentioned. In the discussion of proteins, the Hofmeister series is given prominence while Loeb's name is not mentioned once. The long lists of references totalling about 120 pages would be better adapted for the biologist if the references were given in the order of increasing difficulty.

The book does not fill the need of the practitioner who wishes to understand and apply the findings of physico-chemical research—it was not written for that purpose. As the authors say in the preface, it is intended for research workers in biology and medicine.

MURRAY J SHEAR.

THE INTERNATIONAL MEDICAL ANNUAL. A Year Book of Treatment and Practitioner's Index. Forty-first year 1923. WILLIAM WOOD & Co, New York. \$5.00 net.

The recent 41st yearly edition of the Medical Annual is a splendid summary and abstract of the important work and productions of the past year. Of special value are the articles on team work in consultation, the use of the X-ray in the treatment of Basedow's disease and malignancy, early reduction of congenital dislocation of the hip, reduction of salt intake in hypertension, the use of quinine, early signs of carcinoma of the breast, foreign protein therapy, basal metabolism, reduction of intracerebral pressure with hypertonic solutions, localization of brain tumors by encephalography, epidemic encephalitis, epidemic hiccup, luminal in epilepsy, infant feeding, rickets, biliary drainage, newer methods in the treatment of arthritis, value and methods of transfusion, protein treatment of asthma, insulin therapy in diabetes, and treatment of nephritis.

M. A. RABINOWITZ.

PHYSICAL DIAGNOSIS OF DISEASES OF THE CHEST By JOSEPH H. PRATT, A.M., M.D., and GEORGE E. BUSHNELL, Ph.D., M.D. Octavo of 522 pages with 166 illustrations. Phila. and London, W. B. Saunders Co., 1925. Cloth, \$5.00.

The authors present an excellent book on the subject. Anatomy, physiology, pathology, and physics are well correlated in their relationship to the physical findings in the heart and lungs in health and disease. The well known diseases of these organs are considered in detail, but scant consideration is given to the less well known conditions. All the modern means of diagnosis are given sufficient consideration for their value to be clearly recognized by physicians. This book will be of value to any person interested in the diseases of the chest.

J. ARTHUR BUCHANAN

PREVENTIVE MEDICINE. By MARK F. BOYD, M.D., M.S., C.P.H. Second edition, revised. Octavo of 429 pages with 135 illustrations. Philadelphia and London, W. B. Saunders Company, 1925. Cloth, \$4.00.

In this excellent book the author has endeavored to present briefly, the salient features of modern preventive medicine. The material included represents the minimum knowledge in this field that should be expected of a student of medicine or a general practitioner. The author contends and truthfully so that the profession as a whole is neglecting the opportunity to play the predominant rôle in the new field of preventive medicine and public health. He hopes the book will bring home to all the necessity for a change in this respect.

The subject matter is written in a clear concise style. The literature has evidently been carefully consulted so that the viewpoints expressed are brought entirely up to date, making a most useful book, presenting a rather complicated subject in a short yet sufficiently complete and simple manner.

Section I covers the epidemiology of diseases due to invading microorganisms, Section II deals with deficiency diseases, Section III with occupational diseases, Section IV with diseases arising in the puerperal state, Section V with diseases transmitted from parent to offspring, Section VI with special aspects of hygiene and sanitation, Section VII with demography, Section VIII with public health administration.

JOSEPH C. REGAN

THE CHEMICAL AND PHYSIOLOGICAL PROPERTIES OF THE INTERNAL SECRETIONS By E. C. DODDS, Ph.D., B.Sc., M.B., B.S. and F. DICKENS, M.A., Ph.D. Octavo of 214 pages. London, Humphrey Milford, New York, Oxford University Press, 1925. Cloth, \$2.50. (Oxford Medical Publications.)

A summary of the physiological and chemical properties of the internal secretions is presented together with workable descriptions of the preparation and standardization of the products. A chapter is given to the secretions of each of the following organs: pancreas (insulin), pituitary body (tethelin, pituitrin, hypophyseine), thyroid (iodothyronin, iodothyreoglobulin, thyroxin), ovaries, suprarenals (adrenaline, adrenin, epinephrine). Chapter VI is entitled "Miscellanea" and deals briefly with secretin, the parathyroid glands and spermine.

The authors say in the preface "This volume has no claim to originality other than that it contains, under one cover, a summary of the literature dealing with the chemical aspects of the internal secretions. In the course of preparation (of a series of lectures) we were impressed by the vast amount of references to be consulted, and by the absence of any collected account of the original papers. On the completion of

this task we were tempted to publish our findings, mainly with the view to saving other workers the somewhat dreary task of looking up all the original researches."

The authors have accomplished a worth while task. Research workers especially, both in the laboratory and in the clinic, will find this volume useful and convenient.

MURRAY J. SHEAR

EYE, EAR, NOSE AND THROAT MANUAL FOR NURSES. By ROY H. PARKINSON, M.D., Visiting Oculist and Aurist to St. Joseph's Hospital, San Francisco, California. Illustrated. The C. V. Mosby Co., St. Louis, 1925. Price \$2.25.

As the author states in his introduction, there has been a real need for just such a manual. The general arrangement of the text is to be commended, while the illustrations serve their purpose well, a few more diagrams and illustrations of this kind would be helpful.

It is very important that there be erroneous or misleading statements in a textbook for nurses, for it is true that the pupil nurse accepts entirely that which her medical teacher tells her. This is even more so when she obtains her information from a textbook.

It is hoped, therefore, that another edition will appear in which the author will exercise more latitude in his selections of the instruments used for operations, and that more space and attention will be given to some of the following:

The after care of patients, who have just been operated upon for ethmoid and sphenoidal sinus disease, is of much more importance to the nurse than the instruments used. This is also true of tracheotomy cases, where nursing is of so much value and where a thorough understanding of what has been done and what to expect is so essential.

The statement that Bronchoscopy is a very rare procedure, carries with it the intimation that the nurse need know nothing about it. This part of the text it is hoped will receive further attention.

Throughout the book there is an evident lack of real nursing information.

THE WRITING OF MEDICAL PAPERS By MAUD H. MELLISH. Second edition, revised. 12mo of 168 pages. Philadelphia and London, W. B. Saunders Company, 1925. Cloth, \$1.50.

The average medical writer needs this little book just "like a baby needs its mother," with apologies to Beethoven. Mrs. Mellish has made a careful study of the literary shortcomings of us doctors, quite a monumental task, you may be assured. Her book is, therefore, of inestimable value to all who are interested in the technic of medical writing.

Certain important phases of medical writing do not, however, receive the complete consideration that they deserve. For example, you could not learn how to produce really good tabulation on the basis of information contained in this book. Now tabulation is frequently the cream of an article, as distinguished from the accompanying verbal apple sauce. Tabulation need not necessarily look like a Chinese puzzle, it may be made as clear as a tobacco advertisement. In the matter of references the style of citation employed by the American Medical Association publications, certainly an important matter, is treated like a stepchild.

There is so much of real value in this book that such defects as those mentioned above shrink into insignificance. Certainly "The Writing of Medical Papers" has found its place on the reviewer's one-yard book shelf.

FREDERIC DAMRAU

NEW YORK STATE JOURNAL of MEDICINE

VOL 26, No 9

NEW YORK, N Y

MAY 1, 1926

THE PHYSICIAN AND THE PATIENT OF THE FUTURE

By Wendell C Phillips, M D
NEW YORK CITY

A review of the President's Inaugural Address before the American Medical Association, at its seventy-seventh annual session at Dallas, Texas, April 20th, 1926

Dr Wendell C Phillips spoke for the entire medical profession of the Nation when he pictured both the physician and the patient of the future in his inaugural address as President of the American Medical Association. His vision was not an idealism of a far distant future, but an advance showing of what is already in existence, demonstrated by small groups of practical men, and sponsored by the leaders of the medical societies of the Nation, the States, and the Counties. His vision is the unfolding of past experience, and is founded on the sure basis of historical facts and the trends of action of the human mind. He has read the signs of the times and planned a system of the practice of medicine that considers the patient and the community as well as the physician. He has recognized the mutual interdependence of the people and the doctors, and has outlined practical ways by which the doctors may fulfill the high ideals of their calling, and the people may receive the full benefits of medical service. It was indeed a happy thought to consider the patient equally with the physician of the future.

THE HERITAGE OF THE FUTURE PHYSICIAN

Dr Phillips opened his address with a consideration of "The Heritage of the Future Physician," as revealed in past history. "The marvelous achievements of the men of medicine to day," he said "are largely the outgrowth and fruition of similar achievements of the founders of our art. The history of no other science contains brighter pages than those illumined by the scientific conquests of the great men of medicine. The new developments in medical science have created the necessity for changes in modes methods and economies so far reaching as to affect all phases of national family, and individual life. The physician both of the present and of the future must be an integral part of our civilization and much concerned with its changes."

After quoting some of the high lights of medical progress, he says

"The future may bring about the complete eradication of diphtheria, scarlet fever, whooping cough, and possibly all the exanthems, while yellow fever, typhus fever and all plagues are falling before the gigantic march of preventive medicine, based on bacteriologic discoveries."

"This has been the contribution of the physician to the march of human progress. Truly, neither the physician of the present nor the physician of the future need ever blush when contemplating his professional heritage."

CHANGES IN MEDICAL PRACTICE

Dr Phillips then spoke of "Changes in Present-day Medical Practice," and of the rise of departments of health and lay organizations whose object was to make practical application of the newer discoveries in preventive medicine whose usefulness time alone could demonstrate.

"We build on the experience of the past. The rapid strides in medical discoveries of the last two generations, together with the more practical employment of sanitation and preventive medicine, have already effected great changes in the actual duties of the practicing physician. The daily round of our immediate predecessors was made up largely of the treatment of infectious and contagious diseases. The day book of the family physician usually recorded visits to families for the treatment of measles, scarlet fever, diphtheria, typhoid fever, or malaria only. He was educated to treat disease. He knew little of preventive medicine, sanitation, or hygiene, nor did his medical education provide such knowledge. Older living practitioners know of the changes which mark the new era only by keeping abreast of the times."

"National, state, and municipal departments of health have gradually become powerful and controlling factors in preventive medicine, sanitation, and hygiene. Health and welfare or-

ganizations, both national and local, have also invaded the field of preventive medicine. Great industrial organizations have introduced various health measures, believing it to be for their own best interests from an economical standpoint, as well as for the benefit of the hundreds of thousands of employees. Pay clinics and group practice have made some slight imprint on the modes of practice of to-day. Furthermore, the publicity work of all these agencies, together with that of our own Association, has gradually created a demand from the public for more information regarding personal health. The outcome of these measures has led to confusion regarding not only the present but also the future of medical practice. But the confusion of the present need never become chaos in the future, provided the medical profession prepares to meet the demands of the patients of the future."

HEALTH EDUCATION

Now that medical science has advanced to such a stage that preventive medicine is entirely practical, the next step is to bring a knowledge of that science to the people and to the doctors themselves. The production of the new medical ideas is assured, their sale to the great mass of distributing agents—the doctor, and to the people, the buyers—is the next great activity of the medical profession. Health education is the basis on which preventive medicine rests.

Dr Phillips considered health education from two standpoints: 1, that of the public, and, 2, that of the physician.

HEALTH EDUCATION OF THE PUBLIC

Regarding "Health Education from the Standpoint of the Public," Dr Phillips said:

"The new era in medicine which the physician of the future must be prepared to enter must also rest on the foundation of a wide and comprehensive plan of personal and public health education. Professional policies, narrowly conceived, can never successfully oppose the rightful interest of the public. The failure properly to educate the public regarding the achievements of medicine and its importance in the preservation of life and the prevention of sickness may be considered as such a policy."

A CHALLENGE

The President called attention to the great demand on the part of editors of periodicals for medical articles suited to lay readers, and quoted the criticisms printed in the *Saturday Evening Post*, and reproduced in the *NEW YORK STATE JOURNAL OF MEDICINE* on page 219 of the March 1st issue. He read the following challenge of the *Saturday Evening Post*:

"S. I. F. the American
Med. Co. made such a

good start along these lines, ought to take up the matter in a big way and work out a comprehensive program which would unify the efforts of the agencies already in the field, and cover the lay press of the whole country."

Regarding this quotation, Dr Phillips said:

"This statement is the challenge to organized medicine. I pledge its fulfillment so far as lies within my power, and I sincerely hope that influential laymen of our country will accept the challenge. I am proud to state with the greatest emphasis that the medical profession is well able to supply the brains for any and all nation-wide efforts for individual and community health education that the great business publications and the advertising world will undertake to promulgate and finance."

EVERY PHYSICIAN A HEALTH TEACHER

"Physicians until recently have contributed insufficiently to public health education. To day every licensed physician is being urged to prepare himself to teach his own patients the principles of health. Sufficient progress has already been made to warrant the statement that the field of public health education must and should be invaded by the physician. Organized medicine has approved this measure."

As evidence of the educational activity of the American Medical Association, Dr Phillips quoted the establishment of the monthly publication, "Hygeia," for lay readers, the promotion of periodic health examination, and the successful campaign to purify the pages of the leading dailies of quack advertisements. He also commended the annual address of Governor Alfred E. Smith of New York as a model example of a wise treatment of public health problems by the civic authorities.

THE PHYSICIAN IN HEALTH EDUCATION

Dr Phillips then took up the subject of "Health Education from the Standpoint of the Physician," and said:

"The proposed campaign of public health education will surely create a demand for new contacts between patient and physician. Physicians must give a new significance to the word patient, for in the new order of things both sick and well people must and will be recorded in the lists of their physicians. In one of his recent addresses, Dr George E. Vincent has called attention to the demands which this newly informed public is likely to make. 'They will demand that their needs should be met,' he has said, and he warns that unless the medical profession shall organize to meet the demand in the proper spirit, various forms of state medicine are likely to become the order of the day. 'No thoughtful person would welcome the extension of state medicine to the legitimate and necessary...'"

activity, but if private initiative and voluntary cooperation fail, it may be impossible to resist the demand for governmental intervention' in the practice of medicine. In other words, the state may be called on to organize and control not only methods of medical treatment but also the financial remuneration of the physician. I believe that this is unnecessary, but it surely will come unless we ourselves give heed to the coming needs and formulate our modes and methods to meet this demand in the spirit of true medicine. For medical agitators to stand on the housetops and shout defiance to state medicine will never solve a problem which can only be solved by perfecting a better way. The better way is to promote by precept and example the vast importance of maintaining the personal relationship of physician and patient. This is an essential fundamental in medical practice."

"The physician of the future must prepare himself educationally, morally, psychologically and sociologically, to make the painstaking intimate personal contact with his individual patient so effective, outstanding and unassailable that no other form of medical practice will be permitted by the layman himself."

"What have I described? No new word need be coined for the answer. The future health needs of the public can best be supplied by a more humane, painstaking, better qualified, general practitioner of medicine."

"The family physician should remain the foundation of medical service. His outlook, functions, and training need modification to meet changing needs. The field will be great and the opportunity for service boundless. The loyal service of the ideal general practitioner of medicine will go far to limit the advent of insurance methods of treatment, state systems, industrial groups, and other socialized principles which the true psychologists and humanists in medicine look on as mechanistic, soulless, bureaucratic, card index systems, discounting the spirit of individual relationship characterized by the better way."

THE PERIODIC HEALTH EXAMINATION

Discussing the periodic health examination as a measure of preventive medicine and public health, Dr Phillips says

"This family physician must educate his patients and community in preventive medicine and be to some extent a health administrator. His chief role and his chief service will be to keep his patients well. Evidently, such service can be made possible only by maintaining intimate, clinical information, well recorded, regarding every man, woman and child who seeks his service. And every man, woman, and child in every community should have his health recorded in of our citizens his family physician. Too many of changes." carry through life with only

fairly good health, and while they accomplish their daily duties, these fairly well persons may never know the exuberance and happiness of perfect health. Hence, one goal of the future practitioner of medicine will be the attainment and maintenance of exuberant health, which is the inherent right of every person. A higher average of overflowing good health means a higher average of happiness, comfort, usefulness, and economic value of the individual. The superman will never materialize without superhealth."

EDUCATION OF THE PHYSICIAN

Regarding "The Education of the Future Physician," Dr Phillips says

"The education of the physician of the future must provide instruction in the art of medicine as well as in the science of medicine—not less of science, but more of the art is the educational need of the hour. This view of medical education of the physician presages the future output of medical men whose scientific thinking will be less in mechanical lines, less in the technic of the laboratory, and more in the terms of the humanist. He must be taught to think more in terms of life, health, and humanity, than of disease and death."

"The medical education of the present places too much emphasis on the material and too little on the spiritual phases of medical practice. The student of medicine must be taught how to care for and advise the man as well as the patient. To this end, nothing need be done to disturb the high standards of medical education which the American Medical Association has set. It is necessary, however, that greater elasticity be given through proper modification of the present curriculum and policies of medical education."

Dr Phillips then enumerates a list of subjects of which the modern physician should have fundamental knowledge, and says

"If our future practitioner fails in these things, his 'place in the sun' will progressively diminish, and his rôle will be invaded by industrial, state, and various group practices,—which will be a great disadvantage to our inhabitants. The family physician should remain the foundation of medical service."

"In view of these added requirements in the education of the future physician, it is unthinkable even to contemplate any lowering of the standards of medical education. Nor should a limited medical training be approved for men who might be willing to practice in rural communities. Any claim for a limited medical training is fallacious in reasoning and untenable, for the reason that the best in medical care is none too good for our lowliest inhabitants, no matter where they reside."

Concerning training in the specialties, Dr Phillips says

"The undergraduate medical school should

limit its teaching to the output of all-round qualified general practitioners of medicine only, and it should in no sense attempt to prepare men for the various specialties. Preparation for all the specialties should be entirely dependent on graduate school of medicine. So far as our country is concerned, courses for specializing may be secured through graduate medical teachings in the universities and post-graduate schools."

"The courses for the majority of the specialties should cover a period of at least three years. In several of the specialties in his country, particularly the eye, ear, nose and throat, examination boards have been created for men who desire to be formally recognized by the national societies. Fortunately, it is no longer necessary for men to seek the graduate training in foreign countries. Under this scheme of education, every specialist must first receive the preliminary training required by the general practitioner of medicine."

NEED OF HOSPITALS

Regarding the "Need of Hospitals," Dr Phillips says

"Hospitals or similar facilities for the application of the refinements in diagnosis and treatment should be available in all communities, and particularly in rural districts. At present 25 per cent or less of the practitioners, both city and country, have hospital facilities. It seems somewhat difficult to supply proper hospital facilities in many rural communities, but our proposed extensive program of public health education should lead the enlightened laity to meet this demand. Every physician should be in contact with hospital facilities and experience—his progress in his profession depends on it. In every instance, particularly in rural communities, open staff organizations are preferred, but hospitals connected with medical schools must necessarily be closed staff organizations. It is possible that in other hospitals the open-staff organization could be made practicable by having a so-called executive staff or regular attendants in all departments who would be responsible for the character of the professional conduct of the hospital, and this staff would be supplemented by an auxiliary or associated staff properly classified and made associate members of the executive staff departments. This would afford every worthy physician of the community a hospital

connection, but he would be obliged to follow the regulations of the hospital made and adopted by the executive staff."

SPIRITUAL OUTLOOK

In closing, Dr Phillips spoke of the spiritual outlook of the future physician, and said

"Let us hope that the physician of the future will be fully conscious of the vastness of the causes which he must advocate and the usefulness of the deeds he must accomplish, that he may have wisdom, poise, and capacity of understanding that will breed in his patient an extraordinary confidence and esteem, that he may have a vision of a healthier, happier world which will blossom into unheard-of activity. May we hope that to this end he will dedicate himself 'through service to all that will advance and maintain and increase the sum of human happiness'."

"Every man who looks toward the future is charged with being a dreamer. But the verdict of history has always been that the onward march of science, religion, and civilization has been led by dreamers. I have ventured modestly to tell my dream, knowing that it will find a thousand responsive cords in the hearts of my colleagues whose ambition and passion are to serve our fellowmen."

"Who dreams shall live. And if we do not dream,
Then we shall build no temple into time
Yon dust cloud, whirling slow against the sun,
Was yesterday's cathedral, stirred to gold
By heedless footsteps of a passing world
The faiths of stone and steel are failed of proof,
The king who made religion of a sword
Passes, and is forgotten in a day
The crown he wore rots at a lily's root,
The rose unfurls her banners o'er his dust.
The dreamer dies, but never dies the dream
Though Death shall call the whirlwind to his aid,
Enlist men's passions, trick their hearts with hate,
Still shall the vision live. Say nevermore
That dreams are fragile things. What else
endures

Of all this broken world save only dreams!

"DANA BURNET"

Every physician will wish to read the entire Inaugural Address of Dr Phillips. It is printed in full in the April 24th issue of the *Journal of the American Medical Association*.

A SURVEY OF OUR PRESENT KNOWLEDGE OF TETANUS AND ITS TREATMENT *

MATTHIAS NICOLL, JR., M D, State Commissioner of Health
ALBANY, N Y

TETANUS was first made reportable to the State Department of Health in 1918. The facts that I am about to present are based on the analysis of 1,407 deaths from tetanus, in the State including the city of New York, reported to the Division of Vital Statistics from 1907-1921, inclusive. In 1922, the Department began the circulation of a questionnaire among physicians and hospitals reporting cases of tetanus, and thus has been able to make a critical analysis of an additional 262 cases reported up to and including 1925. While it may be contended that the total number of cases, 1,669, concerning many of which very little information has been obtained, is not sufficiently large to

ancies which seem to exist between generally accepted conclusions regarding the prevention and treatment of tetanus and the results of the statistical survey which I shall now present

TABLE I

Mortality from Tetanus in New York State 1907-1925

Year	No Deaths	Mortality rate per 100,000 population
1907	128	1.49
1908	124	1.41
1909	109	1.22
1910	111	1.21
1911	97	1.04
1912	114	1.21
1913	94	0.98
1914	107	1.10
1915	90	0.91
1916	69	0.69
1917	77	0.76
1918	73	0.71
1919	73	0.71
1920	69	0.66
1921	72	0.68
1922	79	0.74
1923	69	0.63
1924	68	0.62
1925	60	0.54

form a basis for definite conclusions, especially as regards the results of preventive and curative methods of treatment, they, nevertheless, permit certain inferences which, it must be confessed, I was unprepared for, since they are greatly at variance with personal experience based on extensive laboratory experiments and close, though limited, clinical observations made a decade or more ago.

Those of you who have had the opportunity, which has been denied to me, to study the occurrence, prevention and treatment of tetanus under war and later peace-time conditions, will, I hope, be able to explain the apparent discrep-

* Read before the Annual Meeting of the Medical Society of the State of New York at New York March 31st 1926

TABLE II

Tetanus Mortality by Months (with percentages) 1907-1915 and 1920-1925

Month	No	1907-1915 Per cent of totals	No	1920-1925 Per cent of totals
January	53	5	25	6
February	57	6	20	5
March	48	5	16	4
April	68	7	25	6
May	75	8	34	8
June	98	10	40	10
July	128	13	79	18
August	116	12	45	11
September	98	10	29	7
October	100	10	55	13
November	69	7	30	7
December	64	7	19	5
Total	974	100	417	100

The mortality from tetanus has been decreasing rapidly from 1907 to date (Table I). The rate per 100,000 population in that year, for the whole State, was 1.49, and in 1925, 0.54—a reduction of practically 64 per cent. The rate has fallen with a fair degree of regularity year by year. This can be fairly attributed to no other cause than the more general use of antitoxin as a preventive.

SEASONAL OCCURRENCE

A study of the mortality by months brings out the well recognized fact that during the open seasons of the year, from June to October, tetanus is more likely to occur, due, of course, to the greater chances of infection with the causative organism (Table II).

RELATION OF FATALITY TO INCUBATION PERIOD

An analysis of 220 cases tends to confirm the direct relation between fatality and length of incubation, being almost twice as high among cases with incubation under a week as among those which developed after two weeks (Table III).

TABLE III

Incubation period in days	Totals	Recovered	Died	Fatality rate
0-7	90	15	75	83
8-14	92	36	56	61
Over 14	38	22	16	42
All periods	220	73	147	67

INCUBATION PERIOD CLASSIFIED ACCORDING TO THE SITE OF INJURY

An analysis of the same number of cases, to determine what relation, if any, the site of injury bears to the incubation period, shows a notable preponderance of injuries to the head and neck, in which tetanus developed after an incubation of less than a week, with very little difference as regards short incubation between wounds of the upper extremities and wounds of the lower extremities. The figures, however, are not sufficiently large from which to draw anything more than a suggestion (Table IV)

TABLE IV

Incubation Periods (220 cases) Classified According to the Site of Injury

	Incubation Periods in Days					
	0-7		8-14		Over 14	
	No	Per Cent	No	Per Cent	No	Per Cent
Head and neck	18	55	8	24	7	21
Arms, hands and trunk	43	37	53	46	19	17
Legs and feet	29	40	31	43	12	17
All sites	20	41	92	42	38	17
						220

FATALITY RELATED TO SITE OF INJURY AND INCUBATION PERIOD

On the other hand, there seems to be a definite relation between fatality and the site of injury at all incubation periods (Table V). Thus, in an analysis of 220 cases in which there was injury of the head and neck, there was a fatality rate of 79 as against a general fatality rate following all sites of injury of 67

RELATION OF FOURTH OF JULY ACCIDENTS TO TETANUS

Tetanus has long been associated—and with just cause—with Fourth of July celebrations. Of late years, we have heard a good many congratulatory comments on what is popularly known as the "Sane Fourth." If the occurrence of tetanus, as a result of Fourth of July celebrations, is to be taken as a criterion, it would seem that this State, at least, is quite as insane as formerly

TABLE VI

Deaths from Tetanus occurring in June, July and August, 1913-1917—Classified According to their Presumable Relation to Independence Day Celebrations

Nature of Injury	June	July	August	Totals
Gunshot wound	1	0	0	1
Burn, nature not given	1	0	0	1
Injury, nature not given	0	1	0	1
Wound, nature not given	3	0	0	3
"Idiopathic"	0	1	0	1
Unknown origin	0	3	1	4
Injuries apparently not related to Independence Day Celebrations	17	33	31	81
Totals	22	38	32	92

A consideration of the figures from 1913-1917 (Table VI), shows that out of 92 deaths from

tetanus occurring in June, July and August, only one is known to have been caused by an injury presumably connected with Independence Day celebrations, as compared with 16 deaths for the period from 1922-1925, inclusive. Even if injuries of unknown nature and cases of unknown origin are included, the total which might possibly have had some relation to Independence Day celebrations in the first five-year period is only 11 (Table VI) as compared with 19 in the last four-year period, if we also include, in the latter, cases of unknown origin (Table VII)

FORTY-FIVE CASES OF TETANUS CLASSIFIED ACCORDING TO THEIR RELATION TO INDEPENDENCE DAY CELEBRATIONS, 1922-1925

A study of the nature of wounds, inflicted during Fourth of July celebrations, brings out very clearly the menace of the blank cartridge and toy pistol. I think that you will agree with me that the State should exercise some authority in the form of restriction of the kind of weapons and ammunition which are being used to celebrate our great national holiday. Casual observation would lead to the conclusion that, while the comparatively innocuous old-time firecracker is not so much used by the younger generation, the explosives which are now on the market and sold apparently with little or no restriction, have much more deadly possibilities, even apart from their ability to cause tetanus, than those available a decade or more ago.

PREVENTION BY ANTITOXIN

It is not possible to give an estimate, of any value, regarding the number of preventive inoculations that are now being annually administered. Judging, however, by the number of preventive doses that are going out from the state laboratory the number is very large and constantly increasing, a fact which unquestionably accounts for the great diminution in the number of tetanus cases which occur annually.

That antitoxin not infrequently fails to prevent the disease, in cases of very extensive and badly infected wounds, is generally recognized. It is not so well known that antitoxin is not always a preventive even in the case of comparatively slight wounds. In our series of statistics, it was found that it failed to prevent tetanus in 18 cases, in 13 of which it was said to have been administered on the day upon which the injury took place. Fourteen of these patients died—a fatality rate of 78 per cent. In two instances, however, a statement was made to the effect that the focus of infection might have been other than the wound for which the antitoxin was given. However, in these two cases, the onset of the disease was 14 and 16 days after the administration of the prophylactic dose, which appears to have been sufficient in quantity in all

instances Nine patients received 1,500 units and one was given a second dose of 1,500 units a week after the first. One patient was given 3,000 units at the time of the injury and developed the disease two weeks later The nature of the injuries in these cases are as follows

- 1 Compound fracture of forearm from fall
- 2 Laceration on back of right hand.
- 3 Thumb cut in woods
- 4 Finger caught in chain of hay press (nail lost)

tance of giving a second or even a third inoculation in injuries of this kind It is also apparent that blank cartridge wounds should come in this category I am not prepared to say whether double the ordinary preventive dose should be administered with or without repetition It may be mentioned that, in two instances, the physicians stated that they had reason to believe that the antitoxin given was over a year old If, as is

TABLE V
Fatality Related to Site of Injury and Incubation Period (220 Cases)

Site of Injury	0-7			Incubation Period in Days 8-14			Over 14			Totals		
	Total	Died	Fatality Rate	Total	Died	Fatality Rate	Total	Died	Fatality Rate	Total	Died	Fatality Rate
Head and neck	18	15	83	8	6	75	7	5	71	33	26	79
Arms, hands and trunk	43	39	91	53	31	58	19	7	37	115	77	67
Legs and feet	29	21	72	31	19	61	12	4	33	72	44	61
All sites	90	75	83	92	56	61	38	16	42	220	147	67

- 5 Third degree burns of buttocks, backs of thighs and calves or leg from gasoline explosion
- 6 Multiple wounds of legs from particles of steel, stone and dirt from explosion of pipe in ditch.
- 7 Third degree burns of hand and forearm from gasoline explosion
- 8 Compound fracture of both bones of left forearm from fall into street from tree.
- 9 Cut above ear from fall on cement floor in barn.
- 10 Blank cartridge wound in hand
- 11 Blank cartridge exploded in hand
- 12 Contusion and laceration of hand with fracture of phalanges of two fingers, followed by infection with gangrene in one finger

likely the antitoxin was manufactured at the state laboratory, this would not account for its failure to protect as there is always a surplussage in each immunizing dose to compensate for deterioration in strength

RESULTS OF ADMINISTRATION OF TETANUS ANTITOXIN BY VARIOUS METHODS

An analysis of 262 cases, as to the result of specific treatment by various methods, gives rather surprising results The death rate of all

TABLE VII
Forty-five Cases of Tetanus Classified According to Their Relation to Independence Day Celebrations 1922-1925

Nature of injury	Cases					Deaths				
	1922	1923	1924	1925	Total	1922	1923	1924	1925	Total
Blank cartridge wound	3	5	3	1	12	3	4	3	0	10
Toy pistol wound	0	1	0	1	2	0	1	0	1	2
Gunshot wound	2	1	0	0	3	1	0	0	0	1
Toy pistol or blank cartridge wound	0	1	0	0	1	0	1	0	0	1
Wound from fireworks	0	0	1	0	1	0	0	1	0	1
Firecracker wound	1	0	0	0	1	1	0	0	0	1
Injuries apparently related to Independence Day celebrations	6	8	4	2	20	5	6	4	1	16
Injuries apparently not related to Independence Day celebrations	14	0	7	0	21	10	0	7	0	17
Unknown cause	3	0	1	0	4	2	0	1	0	3
Totals	23	8	12	2	45	17	6	12	1	36

- 13 Injury to head from automobile accident.
- 14 Scalp wound from fall in cistern.
- 15 Scratch on knuckle from piece of tin
- 16 Crushing injury to hand
- 17 Lacerations on head and body and fractures of skull and ribs from railroad accident
- 18 Burns on face, hands forearms, thigh and calf, fracture of humerus and laceration of skin near it

cases is 68 per cent, and of 18 cases in which no antitoxin was used, 100 per cent On the other hand, it is clearly shown that the intraspinal method of inoculation, whether used alone or in combination with one or more other methods, not only did not prove its superiority but resulted in a very high fatality rate, namely 87 per cent in 15 cases, but even more surprising in 14 cases in which it was used in combination with intramuscular inoculations, it gave

It will be noted that in a majority of these cases tetanus followed an extensive wound or wounds which immediately suggests the impor-

a mortality rate of 93. The lowest death rate occurred in nine cases in which all four methods were used, namely, 33 per cent, the next lowest in 22 cases in which the intravenous method only was used, in which the death rate was 50 per cent. The intraspinal and intravenous methods in 37 cases gave precisely the same mortality as that among all cases, mild, severe, treated by all methods and not treated (Table VIII).

TABLE VIII

Methods of Administration of Antitoxin Treatment Classified According to Outcome

Methods of Administration	Total	Died	Fatality Rate
Intraspinal only	15	13	87
Intraspinal and intravenous	37	25	68
Intraspinal and intramuscular	14	13	93
Intraspinal and subcutaneous	6	5	83
Intraspinal, intravenous and intramuscular	27	16	59
Intraspinal, intravenous and subcutaneous	10	7	70
Intraspinal, intramuscular and subcutaneous	2	0	0
Intraspinal, intravenous, intramuscular and subcutaneous	9	3	33
Intravenous only	22	11	50
Intravenous and intramuscular	21	12	57
Intravenous and subcutaneous	10	8	80
Intravenous, intramuscular and subcutaneous	1	0	0
Intramuscular only	40	28	70
Intramuscular and subcutaneous	7	5	71
Subcutaneous only	20	14	70
No serum used	18	18	100
Unknown	3	1	33
All cases	262	179	68

A summary made of the same cases, grouped according to the results obtained by each method, whether alone or in combination, gives the most favorable place to that series of cases in which the intravenous method was included, namely 56 per cent fatality. There is apparently little choice as between the other three methods, alone or in combination. When four methods were used, the number of cases being small, the lowest fatality rate occurred, namely 33 per cent, the next lowest fatality rate occurred when three methods were used, 57 per cent (Table IX).

TABLE IX

Summaries—Fatality Rates According to Methods of Administering Antitoxin

Method	Total	Died	Fatality Rate
Intraspinal	120	83	69
Intravenous	147	82	56
Intramuscular	121	77	64
Subcutaneous	65	42	65
One method only	97	66	68
Two methods	95	68	72
Three methods	40	23	57
Four methods	9	3	33

It may be thought that the comparatively unfavorable results, following the use of the intraspinal method, were due to delay in the use of the method, especially on account of inability to find a physician who was familiar with the

technique. That this is not the explanation is shown by the classification of the cases according to the day of the disease on which the serum was first administered and on which it was first administered intraspinal. This, in brief, shows that the serum was first administered intraspinal fully as early as when given by other methods (Table X).

TABLE X

Cases Classified by Day of Disease on Which Serum Was First Administered and on Which Serum Was First Administered Intraspinal

Day of Disease	Serum First Administered		Serum First Administered Intraspinal	
	Cases	% of Total	Cases	% of Total
1	77	29	40	34
2	60	23	29	25
3	26	10	10	8
Over 3	67	26	38	32
Unstated	32	12	1	1
Totals	262	100	118	100

Another logical explanation for the comparatively unfavorable results of the intraspinal method of administration would be that this method was used more often in the severe type of cases, corresponding with those with a short incubation. That this is true is shown by an analysis of 190 cases, classified according to the incubation period and the method of treatment used (Table XI). This shows that in 51 per cent of cases treated at all periods of incubation, the intraspinal method was used alone or in combination, against 42 per cent of cases treated at all periods of incubation in which the intravenous method was used alone or in combination. While this, to a certain extent, would seem to indicate that the intraspinal method of treatment was put to a more severe test, the differences between the percentages is not sufficiently great to account for the comparatively better results obtained by the intravenous method.

TABLE XI

Cases in Which the Incubation Period and the Method of Administration of Antitoxin Were Known, (190 Cases), Classified According to the Method of Administration and the Length of Incubation Period

Method	Incubation Period in Days			
	No	0-7	More than 7	All Periods
Intraspinal	45	51	43	88
Intravenous	50	42	70	120
Intramuscular	37	37	64	101
Subcutaneous	23	44	29	52
Combinations of all methods	79	42	111	190

CASES IN WHICH ANTITOXIN WAS GIVEN INTRAMUSCULARLY AND INTRASPINAL

The highest death rate, among treated cases, was shown to be in a group of fourteen treated intraspinal and intramuscularly, in which the

mortality was 93 per cent, there being only one survivor in this group (Table XII)

Table XII shows the nature of these cases, the time of incubation and the amount of antitoxin used. While the number of cases is small, the results obtained were discouraging.

223 CASES CLASSIFIED ACCORDING TO AMOUNT OF ANTITOXIN USED IN TREATMENT WITH FATALITY RATES

An analysis of 223 cases, according to the amount of antitoxin used in treatment, seems

CONCLUSIONS

1 Deaths from tetanus in the state of New York from 1907-1925, are but one-third the number which occurred eighteen years ago. This can be attributed to no other cause than the more general use of tetanus antitoxin as a preventive.

2 Deaths from tetanus, as a result of Fourth of July celebrations, are increasing. It would seem advisable for the State to exercise some control over the sale and use of apparatus and explosives now constituting a grave menace to life and limb.

3 The fact that tetanus occasionally occurs after a single preventive dose of antitoxin strongly suggests the advisability of repeating the dose one or more times.

TABLE XII
Cases in Which Antitoxin Was Given Intramuscularly and Intraspinaly

Incubation period in days	Nature of Injury	Day of disease of 1st administration		Amt. of antitoxin (in thousands of units)	
		Any method	Intra spinously	Total	Intra spinously

* 20,000 units given intramuscularly, 10 c.c. given intraspinaly
* * Additional dose of 15 c.c. given intraspinaly

to show an advantage in using massive doses of antitoxin, although the number of cases in which such massive doses were used is smaller than the number in which ordinary or fairly large doses were used (Table XIII). I give these figures for what they are worth, but I am not prepared to advocate, as a result of the showing, massive doses of antitoxin as a routine.

TABLE XIII

223 Cases Classified According to Amount of Antitoxin Used in Treatment with Fatality Rates

Units of Antitoxin	First day of disease			First & Second days of disease (When serum was given on 2nd day)			All Days		
	Total	Died	Lat	Total	Died	Lat	Total	Died	Lat
1,000-29,000	53	39	74	59	41	69	57	42	74
30,000-99,000	25	17	68	58	45	78	112	82	72
100,000 & over	2	1	50	11	5	45	54	23	43
223 cases	80	57	71	128	91	71	223	147	66

in all severe and extensive wounds, and possibly the advisability of administering twice the standard preventive dose at the first inoculation.

4 An analysis of 262 cases of tetanus, in which the method of treatment is known, fails to show greater value of the intraspinal method over the intravenous alone or in combination.

5 There seems to be some indication of the value of massive doses of antitoxin—this matter is worthy of further study.

MORBIDITY IN OBSTETRICS—ITS REDUCTION BY THE USE OF MERCUROCHROME AS A VAGINAL ANTISEPTIC *

By HARRY WELDAY MAYES, A.M., M.D.

From the Obstetric department of the Methodist Episcopal Hospital of Brooklyn, N. Y.

DURING the last seventy-five years the mortality and morbidity from childbirth have remained practically unchanged, they are just as high to-day as they were before the days of Pasteur and Lister and the discovery of antiseptics. This is a lamentable fact when we consider our present knowledge of bacteriology and its relation to modern surgery.

During the last three years, in the city of Greater New York, the death rate per 1,000 re-

following delivery, not including the day of delivery, and occurring not later than the tenth day, we have considered a "morbidity", this is the standard accepted by the Johns Hopkins Hospital. A large number of the cases have just enough fever to be included in this class, but there are many patients who, with the old technique, had septic temperatures for days and who were in the hospital for weeks and months, still they only counted as a "morbidity". We have endeavored

Table showing a comparison of the morbidity following the use of a 3½ per cent solution of iodine, when applied externally as a pelvic preparation for delivery, with a 4 per cent solution of mercurochrome applied to the perineum and instilled into the vagina.

* During 1924, 268 cases included in the above table had mercurochrome used in the preparation for delivery with a morbidity of 12.6 per cent.

ported births from puerperal septicemia has actually increased. In 1923 it was 0.89, in 1924, 0.99, and in 1925, 1.07, or the equivalent of 138 reported deaths for last year. How many more deaths were indirectly caused by infection, or how many cases were reported as dying from pneumonia, eclampsia, acute cardiac dilatation, etc., when the real cause was a puerperal sepsis, will never be known.

The standard of morbidity used varies with the different clinics and the percentage varies accordingly. Any patient whose temperature reaches 100.4 F (38 C) on two successive days

to analyze our statistics, giving not only the percentage, but also the actual days' morbidity and the fraction of a day for each patient.

For almost two years we have been using a 4 per cent solution of Mercurochrome, in the preparation of the patients for delivery on the Second Obstetrical Service of the Methodist Episcopal Hospital of Brooklyn, and, as time goes on, we are more convinced of the efficacy of the procedure.

In a preliminary report published in the *American Journal of Obstetrics and Gynecology*, July, 1925, I compared its use with that of iodine and the routine soap and water preparation. In the beginning the results were somewhat discourag-

* Read before the Annual Meeting of the Medical Society of the State of New York at New York, March 31, 1926.

ing, as we had a morbidity for the first 300 cases, which was somewhat more than that obtained by the iodine technique. Nevertheless, we had no prolonged sepsis, and cases with bag induction of premature labor, traumatic deliveries and manual removal of the placenta, often had little or no morbidity. Thus we attributed to the fact that these cases usually had one or more vaginal examinations at which time the mercurochrome was used, and cultures, vaginal and cervical, often were positive when taken immediately after using the mercurochrome, but taken an hour or more later, they were usually negative.

Since February, 1925, 680 cases have been delivered on the Second Obstetrical Service with an uncorrected morbidity of 4.4 per cent and a corrected morbidity of 3.0 per cent. This is a reduction of two-thirds of the morbidity published in the previous report. The decrease in the average

as a lochiometra, six as parametritis, four had infected perineums and in the remaining cases the morbidity was of short duration and the actual cause not determined.

There were six maternal deaths in the 1,395 deliveries. One died at the time of delivery from an acute cardiac dilatation, one, moribund on admission, died from hemorrhage due to premature separation of the placenta, one from pulmonary embolus on the seventh day, one from acute yellow atrophy of the liver, another was admitted in poor condition, after futile attempts had been made to deliver her on the outside, and she died before delivery was completed, and the other had an adherent placenta and died from shock and hemorrhage.

Several other hospitals have followed our technique, and for the most part the reports have been very enthusiastic. Dr. Geo. Kornfeld of

Comparison of the morbidity for various operative procedures for the years 1923, 1924 with the morbidity when the mercurochrome was used during 1925. The drop in morbidity during 1924 was undoubtedly due to the fact that 268 cases were prepared with mercurochrome.

number of days' morbidity was 61 per cent as compared with the morbidity of the first three hundred cases, and we have the same reduction when we compare these results with the morbidity for the years 1923 and 1924.

One thousand three hundred and ninety-five cases have been delivered on both services since February, 1925, with a gross morbidity of 6.7 per cent and a corrected morbidity of 4.4 per cent. If we omit the eight cases which were delivered soon after admission and in which the mercurochrome either was not instilled at all, or was instilled only a short time before delivery, we have a corrected morbidity of 4 per cent. Twenty-eight of the patients had conditions not relating to the delivery which accounted for the morbidity. Eight of these had respiratory infections, ten breast complications, four, colitis, four, nephritis, one a phlebitis, and one acute articular rheumatism. Among the sixty-six cases of corrected morbidity, nineteen were diagnosed

the Jewish Hospital of Brooklyn, reports two hundred and ninety-one cases from the ward service of Dr. Beach, with an uncorrected morbidity of 2.4 per cent and a corrected morbidity of 1.7 per cent, and the other service in charge of Dr. Ronsheim had an uncorrected morbidity of between 4 and 5 per cent for the same period and 6 per cent for the year.

Fifty-five cases have been delivered on the ward service of Dr. Polak at the Long Island College Hospital with a morbidity of 7.4 per cent.

Dr. Dowd from the Norwegian Deaconess Hospital of Brooklyn reports 190 ward and private cases with a morbidity of 5.2 per cent. He compares this with 193 cases before using mercurochrome which gave a morbidity of 12.2 per cent. Three deaths occurred without the mercurochrome and none when mercurochrome was used.

It is true that we have well-equipped hospitals, highly trained obstetricians and the latest equip-

MERCUROCHROME IN HEMORRHAGE

It is almost impossible to sterilize the birth canal during an active hemorrhage, and careless measures taken to control the bleeding often result in serious infection.

Placenta praevia—The vagina may be packed with mercurochrome gauze or gauze saturated with mercurochrome. If the hemorrhage is mild repeated installations will do much to reduce the possibility of infection, if an induction, version, or cesarian section is performed.

Postpartum hemorrhage—Vaginal packing with gauze as described above or if this does not control the bleeding, the packing of both the uterus and vagina with mercurochrome gauze is recommended. The mercurochrome tends to overcome the chance of infection and the gauze may be left in 24, 48 or even 72 hours. We have noticed no toxic symptoms from the drug.

Incomplete Abortion or Miscarriage—Vaginal installations should be used the same as during labor. If an operation is necessary the preparation should be the same as for delivery and a strip of gauze saturated with mercurochrome should be inserted into the uterus and removed before attempting a dilatation and curettage. Mercurochrome may be instilled into the uterus, and if necessary the uterus and vagina may be packed with mercurochrome gauze.

THE STAIN

The discoloration of towels, bed-linen, and drapings used in the delivery room, by mercurochrome, is entirely removed by the ordinary

laundry methods. The first laundering may not remove all the stain unless chemicals are used, but with repeated washings it entirely disappears. Thus, although we have used mercurochrome for over two years and our counterpanes and linen have been frequently soiled, none of them have been destroyed or even damaged by the mercurochrome. Our tile, concrete and linoleum floors show no effects of the stain.

Comparison of the average days morbidity per patient for the years 1923, 1924 and the cases delivered after the use of mercurochrome since February, 1925.

Stains on the hands of the nurse or doctor are almost entirely due to carelessness. If proper containers are used for the mercurochrome and if gloves are used for delivery there should be no stain on the hands, but if such should happen it can be removed by the use of acid alcohol (one and one-half drams of dilute hydrochloric acid in eight ounces of 50 per cent alcohol).

If there is a hole in a glove during a delivery or vaginal examination the mercurochrome will stain the finger sufficiently to keep it from being a source of contamination.

CONCLUSIONS

1 We feel convinced that every mother is entitled to the protection offered her by an attempt to sterilize the birth canal before delivery.

2 We have been able to reduce the morbidity from childbirth over 50 per cent by the use of a 4 per cent solution of mercurochrome as a vaginal antiseptic during labor and delivery.

3 Mercurochrome is a valuable adjunct in the treatment of antepartum and postpartum hemorrhages, and in the care of abortions and miscarriages.

4 The technique is simple and it can be used by the midwife or general practitioner as well as by the doctors in the hospital.

5 Vaginal examinations should be the rule when using mercurochrome because they assist in getting the solution in contact with the entire vaginal mucosa and apparently do not increase the morbidity.

6 Vaginal cultures following the use of mercurochrome are sometimes negative for 24 or 48 hours and then show positive growths. The mercurochrome, although not actually destroying all the bacteria, has possibly inhibited their growth for a period of time sufficient for them to be washed from the vagina by the lochia or absorbed by the maternal tissues.

7 Repeated vaginal instillations have had no noticeable effect on either the mother or baby.

ment for the sterilization of gloves, instruments and dressings used in the delivery room, but all this avails little if we neglect or disregard the fact that in a certain percentage of cases the birth canal contains pathogenic organisms which are as dangerous to the expectant mother as those which are destroyed by the sterilization mentioned above

At the onset of labor the vault of the vagina may at times be sterile, but before labor is completed, there are many sources from which infection may have occurred. The doctor, the nurse, or the patient herself may transfer the bacteria from the perineum, labia or lower vagina to the vicinity of the cervix. Then again it is not an uncommon occurrence to see the cervix at the

sprayed or painted with a 4 per cent solution of mercurochrome, and after inserting two fingers into the vagina, the pelvic floor is depressed and a dram of mercurochrome is instilled and worked well into the folds of the mucous membrane and around the cervix or presenting part. This should be repeated at least every eight hours during labor, before delivery, and before all vaginal examinations.

If the delivery is prolonged, or if there is any question of the perineum or vagina being soiled by feces or otherwise, repeated instillations should be made.

If there is a laceration, or if episiotomy is performed, the torn or cut surfaces should be cleared from blood and mercurochrome applied

vaginal outlet during a uterine contraction, or for it to be forced down during the expression of the placenta.

The advance and regression of the presenting part act similarly to the plunger of a syringe, and draw the secretions laden with micro-organisms to the region of the torn and bleeding cervix. If this is a fact, then it behooves us, if we would rob maternity of its horrors, to make an attempt, at least, to sterilize the birth canal.

In the beginning we painted the perineum and instilled the mercurochrome at the time of delivery. The results were not satisfactory, so we developed a rather complicated technique in which the mercurochrome was instilled on admission of the patient to the hospital, if she was in labor, and instillations were repeated at eight-hour intervals. The morbidity dropped over 50

before suturing.

If a cesarean section is indicated, there should be at least two instillations, an hour or more apart, before the operation.

If the membranes are ruptured and the case is potentially infected, or if delivery is attempted and disproportion found to exist, which threatens

per cent in the next 1,000 cases. Then we endeavored to simplify the technique, and we feel convinced that the following method is more thorough, and the morbidity remains low.

TECHNIQUE

When the patient is admitted she is carefully prepared, and the external genitalia, are cleansed with green soap and water, the perineum is

Chart showing the death rate of 1,000 live births for England and Wales from 1847 to 1921. The discovery of antiseptics and the use of douches caused apparently an increase in the death rate. The curve during the last ten years is where it was seventy-five years ago.

the life of the infant, then we would advise the instillation of three ounces of a one per cent solution of mercurochrome into the amniotic sack, and after one hour, the performance of a classical cesarian section.

Daily vaginal instillations of a one per cent solution of mercurochrome aid in the healing of perineal lacerations and add to the comfort of the patient.

To get the best results we have advised the installation of the mercurochrome at the onset of labor or as soon as possible after labor begins, nevertheless, we believe that it is better to use the solution just before delivery, than to use any of the other routine methods of preparation.

The urinalysis showed only a faint trace of albumin and no casts. Wassermann was negative. The blood clotting time was three minutes, forty-five seconds. Blood count was normal.

The patient was put on small doses of chloral hydrate and rest in bed for a few days in order

transfixed with three chromic gut sutures.

In view of the history, I felt that there was a definite possibility of malignancy and therefore placed three radium needles, each containing $12\frac{1}{2}$ mgm of radium, in the bladder, around the base of the growth. These needles were left in place for five hours. The bladder was closed in the usual manner around a large Pezzer drainage tube.

Pathological Diagnosis—The diagnosis from the pathological laboratory at the Woman's Hospital rendered by Dr Alfred Plaut, was "Fibroepithelioma or Benign Papilloma of the Bladder."

Subsequent Course—For three days following operation the patient continued to have very marked nausea and vomiting. The temperature came down to normal on the fifth day—the highest point at any time being 101.8° F.

During the first four weeks there were periods of more or less hematuria through the drainage tube which was removed after two weeks, and also later through the retention catheter. The patient's general condition was good after the first few days—the blood pressure varied between 202/102 the day after the operation, and from then on averaged 160/80. The suprapubic wound was allowed to close slowly by granulation.

On the 29th day of convalescence the patient complained of severe abdominal pain in the region of the bladder and a considerable quantity of blood was passed through the retention catheter.

Case of Ventral Hernia, front view

to try and reduce the hypertension, but without avail. We therefore decided to go ahead with the operation under spinal anesthesia. This type of anesthesia was selected because of the fact that while we prefer in such cases the parasacral, here it seemed inadvisable owing to the inability to properly secure an abdominal field block on account of the ventral hernia and on account of a corpulent person of short stature.

Operation was done on August 18th. The spinal anesthetic consisted of 12 centigrams of Neocaine. This anesthesia was complete and the only ill effects noted were those of a more or less persistent nausea, which not only lasted through the operation, but for three days afterwards.

The ventral hernia and former operative scars rendered exposure of the bladder a rather difficult and tedious matter. In the course of dissection the peritoneal cavity was inadvertently opened twice, but was carefully closed. It was only, finally, by recognizing the deep fascia in the region of Poupart's Ligament on the right side, that we were able, by dissection, to relieve ourselves of the presenting hernia which had dissected anterior to the fascia and finally were able to expose the bladder and obtain a satisfactory field for operation upon it.

The growth was extremely friable and, on handling it came away in three pieces, leaving us with a small pedicle which bled very freely. This was excised and the base cauterized with the actual cautery, thus failing to check the hemorrhage entirely; the base was

Case of Ventral Hernia, side view

ter. In spite of irrigation of the bladder to remove blood clots hematuria and pain persisted, and she was given one ampule of Calcium Chloride intravenously. Following its administration the bleeding ceased almost immediately and

Curve showing the morbidity by months at the Methodist Episcopal Hospital of Brooklyn. During 1924, 268 cases were delivered after the use of mercurochrome, with a morbidity of 126 per cent. 225 patients had the iodine preparation for delivery during the first five months of 1925 with a morbidity of 111 per cent. After June 1st, 1925, all had the mercurochrome technique. Caesarian sections are not included.

8 I do not know whether mercurochrome is the drug best adapted to the use described above,

another may be found to take its place, but I am convinced that the idea is right.

9 We are of the opinion that a trial labor is justified in all borderline cases, that forceps failing does not necessarily mean a craniotomy, or that a hysterectomy should be done because a woman is potentially infected.

10 If the above technique were adopted by the Department of Health, and the use of mercurochrome made compulsory before all vaginal examinations or instrumentations, the same as is now required for the prevention of ophthalmia neonatorum, I am convinced that there would be a drop in the annual death rate from puerperal fever, and that the midwife and general practitioner would invariably wear gloves during their confinements, and their disregard for asepsis, would in part, at least, be overcome by the antiseptic.

In closing I want to thank Dr. Beach and Dr. Humpstone for the privilege of reporting cases from their services.

*A CASE OF PAPILLOMA OF THE BLADDER WITH INTERESTING SURGICAL AND POST-OPERATIVE COMPLICATIONS

By FRANCIS E. DUBOIS, A.B., M.D.

NEW YORK

From the Clinic of the Woman's Hospital, New York City.

THE following case of papilloma of the bladder is reported because of certain interesting surgical and post-operative complications which presented themselves during the period in which the patient was under our care.

A widow, 59 years of age, presented herself for treatment first on September 25, 1924. Except for the fact that her son was suffering with pernicious anemia and her mother gave a definite history of being a "bleeder," there was no other definite fact in the family history of note.

This patient had gone through twelve pregnancies. The second labor was followed by a severe post-mortem hemorrhage. A laparotomy was done in 1896 for retroversion and another in 1911—uterus, tubes and one ovary being removed.

When first seen she complained of hematuria, frequency, and dysuria. Physical examination showed a short, rather stout woman. At this time abdominal examination was negative except for a large ventral hernia, extending on the left side, from the costal margin to the inguinal region and across the midline in the suprapubic region. Cystoscopic examination was negative except for a pedunculated villous growth on the left side of the bladder, about the size of a walnut, arising from the region of, and obscuring the

left ureteral orifice. A diagnosis of "Benign Papilloma" was made and treatment with the high frequency spark advised. For a while the growth seemed to respond to treatments which were carried out at intervals of ten days to three weeks. The hematuria was much diminished and the frequency and dysuria lessened, but after a few of these treatments the growth seemed to increase in size, hematuria and dysuria became again the prominent symptoms and the question of operative interference was considered. Inasmuch, however, as this tumor appeared to be of benign character, we felt justified in trying the high frequency treatment for a longer period, but the patient's symptoms becoming so aggravated, chiefly those of frequency and dysuria, and the growth having reached the size where it acted more or less as a ball-valve at the internal vesical orifice, an operation seemed unavoidable. Inasmuch as there had been an inadequate response to the treatments with the high frequency current, it made us reasonably suspicious of malignancy in spite of a single pedunculated growth in the region of one ureteral orifice.

The patient was admitted to the Woman's Hospital, on the Urological Service, for operation, on August 13, 1925.

On admission the chief points on physical examination were the following. The large ventral hernia, before noted, a blood pressure of 220/120, a negative heart, and negative lungs.

* Presented at the Meeting of the Genito Urinary Section of the Academy of Medicine, December 16, 1925.

Vol 26 No 9
May 1, 1926

sense of legal authority, by consent of those concerned with the disposal of the remains of the deceased, and where objection lies against the act, a course of education and sympathetic and tactful insistence upon the value of and personal satisfaction to those interested in the deceased which results from the autopsy, must be carried on by the physician. If presented in the proper manner to an intelligent person in many instances the objection will be overcome and sometimes willingness will be evinced to have the body opened.

But unless permission be obtained, it must be clearly borne in mind that it is an illegal act to perform an autopsy, in the absence of such statutory authority, for which a cause of action accrues (*Hassard vs Lehane*, 143 App Div 424, 128 N Y Supp 161) and for which damages may be obtained (*Larsen vs Cahase*, 47 Minn 307) or a criminal action may be instituted (Penal Law, N Y, sec 2214 also *Koerba vs Patek*, 123 Wis 453 *Danahy vs Kellog*, 126 N Y Supp 444, *Foley vs Phelps*, 1 App Div 551, 37 N Y Supp 471).

It is no defense in an action for damages for the performance of an illegal autopsy that it was necessary to perform the autopsy to enable the attending physician to determine the cause of death so that he could certify it upon a death certificate as required by statute (*Woods vs Graham*, 167 N W 113).

A hospital which permits an unauthorized autopsy to be made is liable for damages (*Darcy vs Presbyterian Hospital*, 202 N Y 259), but the plaintiff must allege and show that the hospital made, caused or procured the autopsy complained of (*Hasselbach vs Mt. Sinai Hospital*, 173 App Div 89, 159 N Y Supp 376).

In the absence of statutory authority those who are entitled to sanction the performance of an autopsy are, in order of their right, husband or wife, next of kin in the order of their right to administration if the deceased had died intestate and, when the deceased leaves a will appointing executors, they, having the right of possession of the body and the duty of burial, may give permission for an autopsy.

In the ordinary meaning of the term there is no property right in a dead body, property being something which a person possesses and controls to the exclusion of all other persons, something which he has acquired and holds by legal means. Obviously a dead body is not a thing which can be classified as capable of ownership by another (*Matter of Beekman Street*, 4 Brad, 503 *Pierce vs Proprietors, Swan Point Cemetery*, 10 R I 227, *Danahy vs Kellog*, 126 N Y Supp 444).

Yet the disposal of the dead interest mankind to a greater extent than does much which pertains to property itself, and indeed the opinion has grown up in civilized states that there is a

legal right to the person of the dead, to properly dispose of it and to guard against its violation and the law uniformly recognizes this right and any unauthorized invasion of such right is a wrongful act which constitutes an infringement on a legal right and damages for mental suffering may be recovered for if it is the direct, proximate and natural result of the wrongful act (*Larson vs Chase*, 47 Minn 307).

The same idea is present in primitive communities and from family or clan instinct or religious reasons, interference with the rites of sepulcher or with the cadaver are visited with penalties.

The law makes the parent responsible for the disposal of the dead body of a child (*Reg vs Vann*, 2 Div CC 325), or the husband for a wife or wife for husband (*Johnson vs Marinus*, 18 Ab NC 72 *Patterson vs Patterson*, 59 N Y 583 *Secord vs Secord*, 18 Ab NS 78), or the next of kin (*Snyder vs Snyder*, 60 How Prac 368), or the executors (*Patterson vs Patterson*, 59 N Y 583), or the person under whose roof the dead person lies though he may be reimbursed (*Matter of Tierney* 88 Misc. 347 151 N Y Supp 972), or if there be none of these the State through its public officers may dispose of it as provided by law (*General City Laws*, sect 20 *Consolidated laws*, Poor sec 84 *Insane*, sec 63 *Public Health Law*, 110 111).

In New York one has the right to dispose of his own body after death (*Penal Law*, sec 2210). In California it seems that a pecuniary value attaches to a dead body and one cannot dispose of it by will (*American Medicine*, April 6, 1901, p 37). In Pennsylvania one can dispose absolutely by will of his remains and courts will respect and protect the right of disposal or possession.

For New York the case of *Pettigrew vs Pettigrew*, 56 Ab 878, states the prevailing opinion on the subject of the paramount right over a dead body in the order of relationship previously stated.

These references in regard to the right of possession, control and disposal of a dead body seem relevant to establish the foundation upon which the right to deny autopsy rests, as well as to indicate the necessity for statutory enactment to overcome that right when exigency requires it to be done. Also, that how careful the physician must be not to violate through zeal, ignorance or malice this well founded right.

It is necessary for the public good at times that the sentiments pertaining to a dead body and the rights of those who hold them should be set aside and when such is shown by experience to be required, the legislature has placed the power to do so in the hands of proper officials and the courts have upheld the law whenever properly applied. It is this fact which creates a legal relation to the question of autopsy and the conditions under which this power is legally exercised as stated in the succeeding sections of the law.

the patient passed a comfortable night, and from that time on there was no further hematuria during her stay in the hospital. A second dose of Calcium Chloride was given two days later. Calcium Lactate was administered by mouth in 10 gr doses twice a day, for six days.

The blood count the day following this attack of rather profuse hematuria was—Reds—2,480,000, hmgb 60%, W B C—7,800, Polys—80 and Lymp 20. A rather interesting fact was, that the blood clotting time—four days after the attack of bleeding—was 3 minutes and 30 seconds, and after the patient had been on Calcium Lactate for several days, the clotting time was 8 minutes and 30 seconds. Patient was discharged on October 10th with wound healed and general physical condition good.

Two subsequent cystoscopic examinations

showed a normal bladder except for gradually diminishing congestion, edema, and a small slough at the site of the former growth.

Summary—Before concluding the report of this case I wish to briefly call attention to a few points which seem to me to be of interest.

In the *first place* the benign papilloma of the bladder failed to respond to the high frequency current, necessitating surgical intervention.

Secondly, a patient with essential hypertension, necessitating some form of local anesthesia.

Thirdly, a very large vernal hernia which greatly complicated any operative procedure on the bladder.

Finally, a marked secondary hemorrhage which was apparently controlled by Calcium Chloride.

Whether or not this patient is a "bleeder" is, however, a matter for conjecture.

THE MEASLES YEAR

To the Editor of the New York State Journal of Medicine

The discussion of the measles problem in your April 1st issue was very timely. Dr Godfrey's prophecy that nineteen hundred and twenty-six would be a "measles year" has proved true with a vengeance. In the city of New York during the first three months of this year over 23,000 cases of measles were reported, so that I should estimate that about 100,000 occurred.

The number of deaths reported as due to measles gives a very inadequate idea of the damage done, as most of the deaths are reported as due to the complicating pneumonia. A more accurate idea may be obtained by comparing the weekly incidence of measles, and deaths from broncho-pneumonia in infants and young children. The curves are nearly parallel. As epi-

demic catarrh was prevalent about the same time, it served to add fuel to the flame.

The advice to parents to protect their young children from contact with all persons who have "colds" is sound, but exceedingly difficult to carry out. The use of convalescent serum is valuable in institution but will not prevent the spread of the disease in the community. Of course the difficulty lies in the fact that the disease is most communicable at a time when its presence is not suspected. The spread of the highly communicable diseases of childhood can only be prevented by the *active* immunization of infants.

CHARLES HERRMAN, M.D., New York

Editor's Note For an article by Dr Herrman on active immunization against measles see this JOURNAL, Vol 23, No 3, March, 1923, page 93.

THE LEGAL RELATION OF THE AUTOPSY

By K SELLERS KENNARD, M.D.,

Assistant Medical Examiner City of New York

IN the field of medical practice the autopsy has always been the culmination of scientific endeavor in the quest for knowledge, as therapy has been on the part of the profession that of the humanitarian efforts to relieve suffering.

The exact study of disease is best effected only with the section and examination of the dead body, and from the days of earliest investigations to the present time this procedure furnishes, on the one hand, the only means of the exact determination of the cause of death, and on the other, a never ending source for contention and litigation from those who are ignorant of the law or of the exact purpose for which autopsies are performed.

It is to be expected that the majority of the laity will raise objections to a post-mortem examination, for, as they are unappreciative of its purpose except in a general way, they are blinded by sentiment and cannot or will not understand the ultimate benefit to be derived therefrom. And we must admit that, in some cases, scientific zeal or mere curiosity or pride of opinion sometimes give just cause for this resentment and protest, for neither can ever form a valid excuse for overriding the humane sentiment or religious feelings which attach to a dead relative or friend.

The performance of autopsies for the purpose of instruction or for statistical reasons, while of inestimable value, can only be made, in the ab-

aforesaid medical colleges, schools or universities shall have a priority claim for the purpose of teaching anatomy

An important question arises under this section. While it gives morgues and other institutions the right to deliver any corpse in their possession, not placed there by friends or relatives for keeping or burial, to medical colleges, and to hospitals the right to hold an autopsy upon a corpse unless claimed within forty-eight hours after death, there seems to be placed upon these institutions the obligation to make reasonable inquiry to locate relatives or friends of the deceased. In *Burke vs N Y University*, 179 N Y Supp 626, an action for alleged unlawful dissection, a complaint is demurrable when it alleges that plaintiff "had left their address in order that they might learn if anything had happened to their father or of his death," but does not state with whom or where the address was left, thus placing upon plaintiff the duty of proving that the institution had knowledge of the existence of relatives. In *Newman vs Stewart*, 127 N Y Supp 866, it is only after a reasonable inquiry has been made for relatives, that consent of friends to autopsy will suffice. *Findley vs Atlantic Transportation Co*, 220 N Y 249, relates to the control of a dead body and action for damages for improper disposal at sea and awarded damages to plaintiff.

What constitutes a reasonable inquiry for relatives or friends under this section is largely a question of fact but, where it was not shown what, if any, effort was made to discover the relatives of a dead person, except that the name of a woman was entered as "friend" in the hospital records it was not a compliance with a statute permitting hospitals to deliver bodies for dissection or to hold a post-mortem (*Newman vs Stewart*, 127 N Y Supp 866).

Nowhere does existing law grant authority specifically at least to any official to perform an autopsy without consent in case of suspected infectious disease. Yet it does seem that this is a most important, and at times a vital thing to a community. The Health Department of any locality, concerned as it is with the prevention and spread of disease, should certainly be informed if there be present in the community, any obscure, unusual or unknown disease, liable to become epidemic in character, or if there be present any known infectious disease, that upon its discovery, steps may be taken to prevent its dissemination. And this information should not depend solely upon clinical sources, for autopsy will disclose before physical signs or symptoms occur, the presence of such disease, if thoroughly performed and its chemical, bacteriological and histological adjuncts properly utilized. Numerous deaths occur in the pre-explosive stage of epidemics which escape proper diagnosis, which if investigated by

autopsy would save communities many lives and more dollars.

Judge Roberts in a Maryland case well stated the situation when he said, "The spread of infections and contagious diseases is very apt to occur in a thickly settled community. It is therefore the part of wisdom to watch with vigilance every indication of their appearance, and to investigate the causes which might in any probability produce them. The cause of death must be ascertained, so that means may be adopted for the prevention of other deaths from the same source. The evidence before us exhibits the case of a public official whose duty it is to find out and certify the cause of a death which is brought to his notice" (*Young vs College of Physicians and Surgeons*, 81 Md 358 32 A M). A possible solution would be an enabling act to allow the Commissioner, or Board of Health to authorize an autopsy where the public health may be threatened.

(e) Laws, 1925 N Y chap 139. In effect July 1, 1925.

An act abolishing the office of Coroner in the County of Westchester and creating the office of County Medical Examiner and prescribing his powers and duties.

Sec 3. If upon such examination the said Medical Examiner is of the opinion that death was due to an unlawful act or criminal negligence, he shall at once notify the District Attorney and the police. He shall upon being authorized by the District Attorney of the County of Westchester make an autopsy.

To the record of such case shall be attached the original report of the Medical Examiner and the detailed findings of the autopsy and inquiry, if any.

The above constitute the special statutes to date, authorizing the performance of autopsies without consent. Wherever the powers of those special statutes are properly applied for investigation of crime or suspected crime or for scientific instruction or research, the courts have uniformly upheld them.

Autopsy is permissible under Section 2213, Penal Law, sub 2.

Whenever a coroner is authorized by law to hold an inquest upon a body, so far as such coroner authorizes dissection for the purpose of inquest, and no further.

The function of a coroner's inquest is to investigate the cause of death where there are reasonable grounds for suspicion that it has been occasioned by crime or violence (*Matter of Bandel vs Dept of Health* (1908), 193 N Y 133 85 NE 1067, *Peo vs Warner*, 104 N Y S 279), or when the coroner receives notice from proper authority as to a sudden death and where there is no medical certificate of death from natural cause or other ground upon which he can

The law does not grant any official unlimited power of autopsy, for such a power could be wielded in a community with disastrous results, but while the limits are sharply prescribed, within their jurisdiction public officials are supreme in the performance of autopsies and are immune from civil or criminal liability.

While it is generally understood by both laity and profession that consent is required for autopsy, both are more or less uninformed as to what conditions render it possible to autopsy without consent and this is quite noticeable in the profession.

The physician is prone to request autopsy for the mere satisfaction of scientific curiosity, and, that in cases which no law gives the right to anyone to perform autopsy without consent. The existence of a difference of opinion between doctors as to diagnosis, the physical effects of dosage, the advent of complication or intercurrent affections are grounds in their opinion to obtain an autopsy. Such is not the fact, and no matter how desirable it may be from a medical viewpoint to investigate such affairs, they do not, without more, fall within the scope of official exercise of power.

The Penal Law of the State of New York, in section 2213, provides that the right to dissect the dead body of a human being exists in the following cases:

Sub—I In the cases prescribed by special statutes

(a) Laws of New York, 1902 chap 577 (in effect April 14, 1902)

An act abolishing the office of Coroner of the County of Erie and creating the office of County Medical Examiner and prescribing its duties

Sec 7 When the Medical Examiner or said Deputy Medical Examiner has notice that there has been found, or is lying within the County of Erie, the dead body of a person who is supposed to have come to his death by violence, he shall forthwith repair to the place where such body lies, and take charge of the same and, upon being authorized in writing by the District Attorney of Erie County, or by a justice of the peace of the town in which such body lies, make an autopsy

(b) Laws of New York, 1915, ch 284, being chap xxii, Title 4 of the Greater New York Charter, comprising sections 1570 to 1571d (In effect January 1, 1918)

Violent and suspicious deaths Procedure

Section 1571 When, in the City of New York any person shall die from criminal violence, or by a casualty, or by suicide, or suddenly when in apparent health, or when unattended by a physician, or in prison, or in a suspicious or unusual manner, shall immediately notify the office of the Chief Medical Examiner,

Autopsies Findings

Section 1571a If the cause of death shall be established beyond a reasonable doubt the Medical Examiner in charge shall so report to his office. If, however, in the opinion of such Medical Examiner, an autopsy is necessary the same shall be performed by a medical examiner.

This law creates an office which supplants the Coroner's Office within the City of New York.

Since the creation of this office as far as the writer knows, but one attempt has been made to test the right of a medical examiner to autopsy without consent. In *Hagan vs Kennard*, plaintiff in suit for damages alleged that an unlawful autopsy was performed upon the body of her son in that such autopsy was performed without her sanction. Mr Justice Martin, Supreme Court, Bronx County Term, dismissed complaint, "No ground for action," as section 1571a constitutes a special statute under which autopsies may be performed without consent.

(c) Code of Criminal Procedure (N Y) L 1892, ch 16 Sec 507, in effect Feb 4, 1892

Death Penalty Who to be present

He (the Warden) shall permit no other person to be present at such execution except those designated in this section. Immediately after the execution a post-mortem examination of the body of the convict shall be made by the physicians present at the execution and their report in writing stating the nature of the examination so made by them shall be annexed to the certificate hereinafter mentioned and filed therein.

(d) Public Health Law Sec 316, sub 1, as amended by Laws of 1925 chap 369, in effect April 2, 1925

This sub-division of the law (too long to be quoted in full), should be consulted by those interested (*McKinney's Consolidated Laws of New York*). The portion of the section which is pertinent to this paper is in effect, that persons having lawful control and management of places where in dead bodies are placed, but not by relatives in the usual manner for burial or keeping, may deliver such bodies to lawfully authorized institutions of teaching, for dissection. But not if the next of kin, within forty-eight hours after death, notify such persons not to deliver the dead body or if the dead person shall have expressed a desire to be buried in the usual manner. Persons so claiming such dead body must prove by affidavit that he is a relative of the deceased and shall forfeit his right of claim if he refuses.

Sec 2 Added by Laws 1925 chap 369, in effect April 2, 1925

The person having lawful control and management of any hospital in which a patient has died may order the performance of an autopsy upon the corpse, unless objection is made to such autopsy by the next of kin within forty-eight hours after death. In case of unclaimed bodies the

The district attorney exhumes a dead body, with or without notice to relatives of the deceased, or any corporation having legal charge of such body by an order from any Justice of the Supreme Court or any County Judge of the county in which the body lies (Section 2215, Penal Law, N Y)

The coroner (acting in his official capacity) exhumes a buried body under section 71, subdivision 4 of the Membership Corporation Law by application to the County Court of the county or the Supreme Court at special term, held in the district. Notice of application for consent of the court must be given at least eight days prior thereto, personally, or at least sixteen days prior thereto by mail, to the corporation or to the person not consenting and to every other person to whom service of notice may be required by the court.

Much simpler in former times was exhumation by the coroner "If the body be buried when he comes, he must dig it up" (Rex vs Ferrond, 3 B and Ald 265)

The medical examiner's office exhumes a body without consent of next of kin by (a) referring the case to the district attorney, who proceeds under section 2215, Penal Law, or (b), by direct application to County or Supreme Court as section 71, sub 4, Membership Corporation Law, or, if consent be given by (c) Court order under above section.

The next of kin exhumes under section 71 (above) by court order.

Courts are loath to grant permission to remove or exhume a dead body and such permission should not be granted without the gravest reasons (In re Adams, 172 N Y Supp 612). If public justice demand it, in the greater interest of society, the application is granted but "a court of equity will not, at the instance of their children, decree them the right to remove her body and place it beside that of her husband" (In re Donn 14 N Y Supp 189, the leading case in America upon this subject Cited, 148 N Y Supp 286 153 N Y Supp 441 172 N Y Supp 613).

THE DIFFERENTIAL DIAGNOSIS OF PAIN IN THE RIGHT LOWER QUADRANT OF THE ABDOMEN *

By H A. BLAISDELL, M D,
JAMESTOWN N Y

Thirty years ago the great controversy at every medical convention was over the medical versus the surgical treatment of appendicitis. It has taken a generation to emphasize to the medical profession, the necessity of early diagnosis and early operation for this disease. Indeed, castor oil and enemas are still being given for those classical symptoms which denote appendicitis. It was inevitable that during this educational period thousands of innocent appendices should be sacrificed. Every experienced surgeon who is honest with himself knows that he has removed the appendix from many patients without relieving the pain upon which the diagnosis of appendicitis was chiefly based. Several years ago, Stanton of Schenectady, published a statistical study of appendectomies performed for the relief of chronic appendicitis. He showed that the cases not relieved were usually those in which the chief complaint was recurrent pain in the right side of the abdomen. *The appendix is usually innocent when pain in this region is unaccompanied by fever and digestive disturbances.* The literature is full of references to this fact and of attempts to classify the causes of pseudo-appendicitis. It is high time that we ceased to cloak our ignorance under the convenient mantles of "neurosis" and "adhesions."

The object of this paper is to emphasize the importance of what the writer believes to be the most common of all the causes of mistaken diagnosis of appendicitis. The more generally recognized errors are those involving the gall-bladder, the right tube and ovary, duodenal ulcer, acute pancreatitis, Meckel's diverticulitis, and luetic gastric crisis. After eliminating all these conditions we still have a large class of patients, usually young women whose right abdominal pain recurs after appendectomy. I believe that many of these remaining cases have been explained by Hunner in his classical studies of ureteral obstruction.

Mistakes are not often made in cases of acute appendicitis. Here the sequence of symptoms—epigastric pain followed by nausea, fever and tenderness in the appendix region—spells the correct diagnosis in most cases. It is the so-called chronic or sub-acute appendicitis with recurrent right abdominal pain as the chief or only symptom which should put us on our guard. In such cases, especially in the absence of gastric symptoms the appendix should not even be accused—still less found guilty, until we have definitely eliminated floating kidney, ureteral calculus, pyelitis and stricture or kink of the ureter. For this purpose we suggest the following routine:

1 Careful history with especial reference to gastric, urinary and menstrual symptoms

* Read before the Eighth District Branch at Buffalo October 7 1925

reasonably form an opinion as to the cause of death, it is his duty to hold an inquest (In re Hull 9 Q B D 689)

Acting under authority of law he may order a dissection of the dead body and may employ physicians for that purpose. And the physician who makes such a dissection is not liable to action for damages by the family of the deceased (Cook vs Walley, 1 Colo A 163 27 Pac 950 Hackett vs Hackett, 26 A 42 Hassard vs Lehane, 135 N Y S 711)

But the physician performing the autopsy who removes parts of the body without parent's consent, and throws them away, such parents may maintain an action against him (Palenzke vs Bluming, 98 Ill A 644), and even though authorized by a coroner to perform an autopsy he must not unduly disfigure the body (Young vs College Physicians and Surgeons, 32 Atl. 177) nor can he remove and retain parts of the body on the ground that the case was an interesting one, without consent of the family (Hassard vs Lehane, 128 N Y Supp 161), but he may, by direction of the coroner or district attorney retain them for evidence (Id., Matter of Wnuk, 200 App Div 731). A coroner cannot order an autopsy upon a dead body except as part of an inquest. He must summon a jury, view the corpse and render a verdict. Otherwise his act is that of an individual and is not an official act and those who act under his orders in such cases (as the physician), are liable for damages (Peo vs Fitzgerald, 43 Hun 35 reversed in 5 N Y Cr 335, not as to coroner's authority but other matters). In the latter opinion it was held that the autopsy may be performed before the jury is summoned. A hospital is liable for performing an autopsy upon a case which would naturally come under the coroner's jurisdiction, if such autopsy is unauthorized by the coroner (Darcy vs Presbyterian Hospital, 202 N Y 259 95 N E 695)

With the exception of those counties in New York State which have abolished the coroner's system, autopsies are performed by officials known as coroner's physicians. They are provided for by statute and when acting outside the scope of their authority are liable to the same action and penalty as any other physician.

Sub 3 Autopsy is permissible under Section 2213, Penal Law

Whenever and so far as the husband, wife or next of kin of deceased, being charged by law with the duty of burial, may authorize dissection for the purpose of ascertaining the cause of death and no further

The interesting case of Winkler vs Hawes, 102 N W 418, discloses that certain questions may arise in this connection

First, having received consent to autopsy but no expressed authority to remove any of the organs or any part of them, may he do so without

liability for damages? It seems that he can, upon the theory that consent to the autopsy implies consent to use all legitimate means to fulfill the purpose of the autopsy, namely, to determine the cause of death. Permission to autopsy implies consent to the performance of the act in the usual manner and if removal of some organ and its temporary retention for further study, is necessary, or if portions are removed for chemical or microscopical study, this being usual at autopsies, the person so doing is guilty of no wrong, provided permission to remove and use them was not expressly withheld at the time consent was given for the autopsy. Nevertheless a condition to consent that no part of the body should be taken away, did not necessarily prohibit the taking of a part to the office of the surgeon if it was duly returned and replaced for burial.

Second Though the autopsy be authorized to determine the cause of death and no further, may the physician not yet having found a cause for death, pursue the autopsy against the demand to close, until the purpose for which the autopsy was authorized, namely, the cause of death, be found

It seems that he cannot. The authority conferred is not an agency but a licence and may be revoked at any time and the physician must stop his autopsy when directed by the family whether he has ascertained the cause of death or not. His remedy is to refuse a certification as to cause of death or to venture any opinion whatever.

Sub 4 Autopsy is permissible under Section 2213, Penal Law

Whenever any district attorney in this State, in the discharge of his official duties, shall deem it necessary, may exhume, take possession of and remove the body of a dead person, or any portion thereof, and submit the same to a proper physical and chemical examination (Peo vs Fitzgerald, 105 N Y 152. Neuman vs Steward, 127 N Y Supp 866). This section was created by chap 500, Laws of N Y, 1889

The district attorney has the right to employ any physician he deems competent to dissect the body, which under this section he desires investigated. In New York City the physician employed is usually a medical examiner or a medical assistant attached to the district attorney's office.

The above constitute the sections of the law of New York relating to autopsies upon dead human bodies

After the dissection the remains must be properly restored (organs replaced, body sewed, cleansed, etc.), and then buried and cremated

In many cases it becomes necessary to exhume a body for autopsy when such is to be performed either by consent, or under special statute and it may be of interest to briefly cite the method of procedure and the source of authority upon which the exhumation depends

The district attorney exhumes a dead body, with or without notice to relatives of the deceased, or any corporation having legal charge of such body by an order from any Justice of the Supreme Court or any County Judge of the county in which the body lies (Section 2215, Penal Law, N Y)

The coroner (acting in his official capacity) exhumes a buried body under section 71, subdivision 4 of the Membership Corporation Law by application to the County Court of the county or the Supreme Court at special term, held in the district. Notice of application for consent of the court must be given at least eight days prior thereto, personally, or at least sixteen days prior thereto by mail, to the corporation or to the person not consenting and to every other person to whom service of notice may be required by the court.

Much simpler in former times was exhumation by the coroner. "If the body be buried when he comes, he must dig it up" (Rex vs Ferrond, 3 B and Ald 265)

The medical examiner's office exhumes a body without consent of next of kin by (a) referring the case to the district attorney, who proceeds under section 2215, Penal Law, or (b), by direct application to County or Supreme Court as section 71, sub 4, Membership Corporation Law, or, if consent be given by (c) Court order under above section.

The next of kin exhumes under section 71 (above) by court order.

Courts are loath to grant permission to remove or exhume a dead body and such permission should not be granted without the gravest reasons (In re Adams, 172 N Y Supp 612). If public justice demand it, in the greater interest of society, the application is granted but "a court of equity will not, at the instance of their children, decree them the right to remove her body and place it beside that of her husband" (In re Donn 14 N Y Supp 189, the leading case in America upon this subject. Cited, 148 N Y Supp 286 153 N Y Supp 441 172 N Y Supp 613).

THE DIFFERENTIAL DIAGNOSIS OF PAIN IN THE RIGHT LOWER QUADRANT OF THE ABDOMEN *

By H. A. BLAISDELL, M.D.,

JAMESTOWN N Y

Thirty years ago the great controversy at every medical convention was over the medical versus the surgical treatment of appendicitis. It has taken a generation to emphasize to the medical profession, the necessity of early diagnosis and early operation for this disease. Indeed, castor oil and enemas are still being given for those classical symptoms which denote appendicitis. It was inevitable that during this educational period thousands of innocent appendices should be sacrificed. Every experienced surgeon who is honest with himself knows that he has removed the appendix from many patients without relieving the pain upon which the diagnosis of appendicitis was chiefly based. Several years ago, Stanton of Schenectady, published a statistical study of appendectomies performed for the relief of chronic appendicitis. He showed that the cases not relieved were usually those in which the chief complaint was recurrent pain in the right side of the abdomen. *The appendix is usually innocent when pain in this region is unaccompanied by fever and digestive disturbances.* The literature is full of references to this fact and of attempts to classify the causes of pseudo-appendicitis. It is high time that we ceased to cloak our ignorance under the convenient mantles of "neurosis" and "adhesions."

The object of this paper is to emphasize the importance of what the writer believes to be the most common of all the causes of mistaken diagnosis of appendicitis. The more generally recognized errors are those involving the gall-bladder, the right tube and ovary, duodenal ulcer, acute pancreatitis, Meckel's diverticulitis, and luetic gastric crisis. After eliminating all these conditions we still have a large class of patients, usually young women whose right abdominal pain recurs after appendectomy. I believe that many of these remaining cases have been explained by Hunner in his classical studies of ureteral obstruction.

Mistakes are not often made in cases of acute appendicitis. Here the sequence of symptoms—epigastric pain followed by nausea, fever and tenderness in the appendix region—spells the correct diagnosis in most cases. It is the so-called chronic or sub-acute appendicitis with recurrent right abdominal pain as the chief or only symptom which should put us on our guard. In such cases, especially in the absence of gastric symptoms the appendix should not even be accused—still less found guilty, until we have definitely eliminated floating kidney, ureteral calculus, pyelitis and stricture or kink of the ureter. For this purpose we suggest the following routine:

1 Careful history with especial reference to gastric, urinary and menstrual symptoms

* Read before the Eighth District Branch at Buffalo October 7 1925

2 General physical examination, and here it should be emphasized that not all cases of ureteral obstruction are followed by hydronephrosis as one would suspect, but on the contrary, as in cases of gall-bladder obstruction, the organ above is atrophic and smaller than normal

3 Urinalysis—wet and stained smears of catheterized or sterile, centrifuged specimens (A sterile sample can be obtained from the male by catching the last portion of urine voided. The same technique can be followed with the female by cleansing the vulva and meatus and catching the last portion of voided specimen by holding a sterile test tube over the meatus.) All specimens to be accurate should be examined immediately. One contaminating bacterium soon produces many in the warm urine

4 Any finding, by the foregoing examination, which points toward the urinary tract, should indicate complete cystoscopic examination, *i. e.*, ureteral catheterization, functional test and pyelogram

Hunner's work, with especial reference to ureteral stricture, which dates back to 1912, has been received with divided enthusiasm by the profession at large. Even urologists are not agreed as to the importance of the entity which he has pointed out. We do know this—that many cases who have been operated upon once or many times for recurrent symptoms—get permanent relief from dilatation of the ureters. Two recent cases will serve as illustrations—case No. 1 who escaped operation as a result of proper investigation is as follows

Case W D Male, age 47 Occupation, loomsetter

Began 13 months ago with sudden, severe cramp like pain in right flank and abdomen with throbbing in penis and right thigh, followed by transient hematuria at intervals since. No burning urination but occasional tenesmus—voiding 12 times per day, but not at night. Had been advised numerous times to have operation and had lived through 60 chiropractic treatments without benefit. X-rays repeatedly negative

His physical examination was negative except for some tenderness in right flank and upper

abdomen. Right epididymis also somewhat enlarged and tender

Urine—Occ hyaline casts and white blood cells present

Cystoscoped, and No. 6 catheter passed to right kidney on January 11th—repeated on February 22d, with No. 6 to both kidneys, and he has been absolutely free from all symptoms since.

Case No. 2 having undergone appendectomy because of lack of preliminary study

Case II I B Female, age 18, was operated upon by another surgeon for pain in right abdomen three years ago without relief. She first came to us two years ago with pain and tenderness in right lower quadrant extending up to flank, and with vaginal discharge. An abdominal exploration was not desired, so vagina was treated locally and patient drifted away until last March, seven months ago, when she came in still complaining of pain in lower right quadrant—she had also had 40 chiropractic treatments. At this time diplococci were found in her urine and she gave history of scanty urine, at times not voiding for 24 hours. The diagnosis of chronic recurrent pyelitis with ureteral stricture was made and cystoscopy performed. The same organism found in right kidney as found in urine. A stricture below pelvis was dilated up to number 6 with relief for a while, and then the pain recurred. After five dilatations both ureters were stretched up to number 13 F and symptoms disappeared

SUMMARY

1 Many cases are still being operated upon for appendicitis which are not permanently relieved

2 Pain in the right lower quadrant, when not accompanied by gastric symptoms or fever points to pathology of the urinary tract as often as to the appendix

3 Any sign or symptom after careful study pointing to the urinary tract is an indication for a complete urological survey

4 Many cases whose symptoms have returned following operation have received permanent relief by dilatation of the ureters

THE PRACTICE OF MEDICINE ACT

The Practice of Medicine Act passed the Senate on Wednesday, April 21st, by a vote of 35 to 12. It had already passed the Assembly by a vote of 95 to 33, and it now awaits the Governor's signature.

The legislators have given serious consideration to the appeals from laymen that all who would practice the healing art should give satisfactory evidence of scientific knowledge to the Department of Education.

The revelations of the State Charities Aid Association regarding the unreliability of the evidence of the upholders of cults doubtless

influenced the legislators to decide to support the Act.

Physicians of New York State have been a unit regarding the principle of a uniform educational qualification for all who would treat cases of sickness, their differences of opinion have been over the means of maintaining that standard. Since the Legislature has decided on a method for the control of the practice of medicine, physicians will wish to aid the cause of public health by helping to carry out the provisions of the Act.

THE PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION

Physicians of New York State are honored by the elevation of one of their number to the presidency of the National organization of physicians, the American Medical Association, after a quarter century of service in the medical societies of his County and State, and later as Chairman of the Board of Trustees of the National Society. He brings to the office a mature judgment based on wide experience, and above all an inherited adaptability for the work of the office.

Dr Wendell C Phillips is descended from an early line of ministers of the Gospel who were preachers because they understood men and the mainsprings of human action and conduct. The pioneer bands of colonists who established the New England States were led by brainy preachers who could direct farming, and commerce, and politics, and fighting as efficiently as they could exhort and interpret with persuasive logic and power, and their characteristics appear in their medical representative of the present generation in whom the spirit of service to his brother physicians and the public is inborn.

Dr Phillips excels in his understanding of physicians and the trend of medical practice. His is a constructive mind. He is a prophet who discerns the signs of the times through his knowledge of the past and the present. His inaugural address is a vision of what medical practice will be in the near future. Its ideals embody the natural aspiration of every physician, and their realization is coming sooner than is apparent to those who look only on the hard and selfish side of human nature.

A review of the President's address appears on page 375 of this issue, but golden texts chosen from its wealth of ideas and expression are worthy of note.

"The maintenance of individual practice in the person of the general practitioner or family doctor is of the utmost importance for the survival and continuation of the family home as the foundation of the Nation.

"The confusion of the present (methods of practice) need never become the chaos of the future, provided the medical profession prepares to meet the demands of the patients of the future.

"Professional policies, narrowly conceived, can never successfully oppose the rightful interests of the public.

"The medical profession is well able to supply the brains for any and all nation-wide efforts for individual and community health education that the great business publications and the advertising world will undertake to promulgate and finance.

"Today every licensed physician is being urged to prepare himself to teach his own patients the

principles of health. The field of public health education must be invaded by the physician.

"Knowledge of the great principles of the preservation of health and of the great historical proof of preventive medicine, will lead legislators and others in responsibility to protect every community against the blandishments of uncensored quackery, the enmity of anti-medical propagandists, and the evils of nostrum medication.

"The proposed campaign of public health education will surely create a demand for new contacts between patient and physician.

Wendell C Phillips, M.D., President American Medical Association, 1926-1927

"Physicians must give a new significance to the word patient, for in the new order of things both sick and well people must and will be recorded in the lists of their doctors.

"There must be less of the machine or mechanical physician, and more of the individual.

"The physician of the future must prepare himself educationally, morally, psychologically, and sociologically to make the intimate personal contact with his individual patient so effective, outstanding, and unassailable that no other form of medical practice will be permitted by the layman himself.

"The future health needs of the public can best be supplied by a more humane, painstaking, better qualified practitioner of medicine

"The family doctor should remain the foundation of medical service. His outlook, functions and training need modification to meet changing needs

"The family physician must educate his patients and community in preventive medicine, and be to some extent a health administrator. His chief role of service will be to keep his patients well

"The superman will never materialize without superhealth

"The practice of medicine is in no wise a business

"The service rendered by a physician may not be considered in terms of finance, but in no sense should our physician of the future offer this as an excuse for slothfulness in the management of his business affairs. Every detail of his newer service in the prevention of disease is of great value to his patient. Health education and conservations are services of value even greater to the patient than the sums paid for helping the body to repair the ravages of disease

"Not less of science, but more of the art of the practice of medicine is the need of the hour. The doctor must think more in terms of life, health, and humanity than of disease and death

"The undergraduate student must be trained to treat the body from the standpoint of health as well as that of disease

"The medical education of the present places too much emphasis on the material and too little on the spiritual phases of medical practice. The student of medicine must be taught how to care

for and advise the man as well as the patient

"In addition to his educational qualifications, both academic and medical, the family physician must be a man of character. His daily life must be a practical expression of honesty, morality, and resourcefulness in service to his patients. He will have a due consideration of his own health and responsibilities, and at proper periods will play, as he works, with well-directed energy, giving and asking half the road and fair play

"Any claim for a limited medical knowledge (for a rural doctor) is fallacious in reasoning and untenable, for the reason that the best in medical care is none too good for our inhabitants, no matter where they reside

"Our proposed plan of extensive public health education should lead the enlightened laity to meet the demand for hospitals

"Every physician should be in contact with hospital facilities and experience—his progress in his profession depends on it

"Public health education should be promulgated by health departments and agencies, by lectures, radio, and film, but it will never reach its highest efficiency until it includes a maximum of direct personal instruction by properly qualified family physicians

"Health education will lead the patient of the future to seek the continued advice and counsel of his personal physician. Cults and other menaces to public health will gradually disappear before the rising sun of enlightened public opinion

"The family physician of the future must have proportionate representation in the councils of his profession. No specialty or combination of specialties, not even general surgery, should be permitted to dominate the health affairs of a community or of a nation"

PRECEPTS FOR MEDICAL STUDENTS

Thoughtful educators feel that the education of a medical student is incomplete unless he is well grounded in the art as well as the science of the practice of medicine

A student may be impressed when he sees a case demonstrated brilliantly before a class, but the learner would also like to know what the patient feels about the professor. A general practitioner called to see a patient for the first time has two ideas vividly before his mind, first, what disease affects the patient, second, what the patient and his family thinks of the doctor, or it may well be that the order of the doctor's thoughts is reversed and he thinks of the patient first and the disease secondly

Dr Wendell C Phillips, President of the American Medical Association, in his inaugural address, emphasized this point when he said, "The thinking of the medical man of the future will be less along the line of the mechanical and

the technique of the laboratory, and more of the humanist"

Medical students of today seldom or ever see patients in their own homes, or meet patients as their servants. A general practitioner serves his patient in the best sense of the word. His attitude is in contrast to that of the authority and command assumed in the teaching clinic. He is called by a patient for the purpose of relieving discomfort—usually physical and always mental also. His principal problem is to satisfy the patient both immediately and in the future. Science alone will never satisfy the patient. There must also be the friendly touch

How shall a medical student learn to think in terms of human interest and sympathy? The best way is by observing how the experienced practitioner meets his patients, talks to them, examines them and comforts them. This

means a revival of the former preceptor system

How the medical school of the University of California has tested this plan is told on page 408 of this issue. The question arises, Can this system be extended to all medical students?

There are 18,000 medical students in the United States. To supply each one with a preceptor would require the services of ten

per cent of the practitioners of the nation. Since 4,500 medical students graduate each year, that number of medical men would be required to act as preceptors if each student spent a month of intensive preceptor work in his course.

If the preceptor system is of great value, the physicians of the country will find a way to make it available to the medical student.

THROWING SAND IN THE PEOPLE'S EYES

When will the people realize the altruistic purpose of physicians in promoting a practice of medicine act?

They will probably continue to believe the get-well-quick fakers as long as they believe the get-rich-quick talkers, and they will ascribe selfish motives to doctors just so long as they call the directors of Savings Banks selfish.

A four-page pamphlet attacking the doctors, that has been widely distributed from the news-stands, reads like a soap-box orator's attack on bank presidents. The keynote of the attack is this quotation:

"If the medical trust is allowed to continue its law-making progress, practically every right possessed by the citizens of this country in connection with the physical care of the body will be taken from them."

No bill that was ever sponsored by physicians ever interfered with the inalienable right of any American citizen to seek healing and comfort

from whatever source of healing he chooses.

No bill was ever passed that forbade any man from investing his savings in wild-cat oil stock or other get-rich-quick scheme, and no man was ever arrested for investing his own money in such a scheme. But many a man has been justly arrested and punished for holding himself out as being able to produce enormous dividends for gullible investors.

No man can ever be arrested for confiding his health and life with any one—doctor or faker—he may choose. Doctors wish to prevent unqualified persons from holding themselves out as being able to produce dividends of health by means of their fake stocks of ignorant manipulations.

The proposed Practice of Medicine law would classify get-well-quick promoters with get-rich-quick fakers.

Those who conjure up the ogre of loss of personal independence are merely throwing sand in the eyes of the people.

COOPERATION OR PARTICIPATION

The word "cooperation" is used so frequently in discussions of public health work that its meaning has become almost trite and formal. It is derived from two Latin words, *co*, together, and *operari*, to work. As applied to physicians in public health work, the word implies that they, and departments of health, and lay organizations shall work together for health promotion.

Cooperation implies an equality of the workers in all phases of the cooperative field of public health. The word may even imply a dominance of one group of workers over another when one group discovers something that another should do, and forthwith seeks to dominate the second worker. Cooperation in the anti-tuberculosis movement, for example, requires team work between three groups—physicians, boards of health and lay organizations. Cooperation implies the ready response of physicians to medical needs pointed out by boards of health and lay organizations, and often in addition it implies a demand that the physician group shall cooperate in a way that is dictated by the two other groups. There

is thus a tendency toward the development of two opposing meanings of the word "cooperate." This change of meaning is nothing new or strange in the development of the language. The word "slave" is Russian, and formerly meant a free man. But when the mass of the people became vassals to the overlords, the word took on its present meaning of servitude.

The word "participation" more exactly expresses the physician's point of view of harmony of action among the trinity of workers in public health. It comes from two Latin terms, *pars*—part, and *capere*—to take,—therefore, to take part. Physicians are ready to take their part in any phase of public health work. Their peculiar field is technical work for which they alone are qualified, both legally and scientifically. Their relation to other groups in anti-tuberculosis movements, anti-diphtheria campaigns, and similar activities is expressed by the word "participation" more happily than by the word "cooperation."

EVERY DOCTOR A HEALTH TEACHER

That meeting of a medical society is successful from which the doctors carry away some constructive thought that recurs to mind again and again. Dr George E Vincent voiced such a striking thought when he addressed the 1925 meeting of the Medical Society of the State of New York on "The Doctor of the Future," and described him as "Every Doctor a Health Officer." Doctor Wendel C Phillips amplified the same thought this year in his inaugural address as President of the American Medical Association when he spoke on the subject, "The Physician and the Patient of the Future," and developed the idea of "Every Doctor a Health Teacher."

Both speakers emphasized the civic duties of the doctor, and warned the physicians that their scepter of dominion in the field of the practice of preventive medicine will surely pass from them unless they assumed the duties of diagnosing threatening ills which are yet afar off.

Departments of health and lay organizations have attempted to do the preventive health work which physicians have neglected, but every official body and organization has fallen short in the execution of its plans because it could not go into the medical market and buy sympathetic medical service. The spirit of medical practice cannot be bought and delivered in an impersonal

way, its only perennial source is the practising physician who is the friend and confident, comforter and priest, to every person of his families. To them the doctor is indeed the health officer and the teacher.

Physicians are beginning to practice preventive and educational medicine through their medical societies. Many phases of the newer practice can be done only by the societies by means of a few leaders and spokesmen, but the ideal set forth by both Dr Vincent and Dr Phillips is that every doctor shall feel a personal responsibility for prevention and education among his own patients. This ideal is rapidly becoming an actuality.

There is a distinct field for each of the three bodies of public health workers—official departments of health, unofficial lay organizations, and the great group of family doctors. The recognition and demarkation of those fields was the outstanding result of the last meeting of the Medical Society of the State of New York.

It is gratifying that the heads of a worldwide lay health organization and of the national body of physicians recognize the essential rôle of the family physician in public health. Physicians will respond to the call that is pointed out to them.

LOOKING BACKWARD—THIS JOURNAL TWENTY-FIVE YEARS AGO

The New York State Journal of Medicine for May, 1901, page 87, carries an announcement of Volume III of the Medical Director the issue for 1901, which says

"The Committee on Publication of the State Association has decided this year to make a new departure in compiling the list of physicians for Volume III of the Medical Directory of New York, New Jersey and Connecticut, soon to be published. The list will include the names of all legally registered physicians of these States as far as they can be obtained, without regard to their school of practice. The reason for this action on the part of the committee is as follows. One of the objects for the existence of the association is to help to enforce the medical laws of the State, not the least part of which duty should consist in the prosecution of illegal practitioners, therefore it is important that the officers and members of the component county associations should have a list at hand which

will give the necessary information as to who are and who are not legal practitioners, in order that the violators of the medical practice acts can be readily located for the purpose of prosecution. The recent decision of the Supreme Court of New York, sustained by the Appellant Division of the same court on appeal, determined the right of these associations to prosecute illegal practitioners and to receive the fines resulting from such prosecutions. Under ordinary circumstances these can be undertaken by the county associations with little or no expense. Officers of county associations should note this fact."

This announcement is of special interest because the Publication Committee evidently expected that prosecutions of illegal practitioners would follow the publication of a list of practitioners. But the prosecutions have failed to materialize, for doctors have not wished to act as detectives, and the lists have never been 100 per cent perfect.

means a revival of the former preceptor system. How the medical school of the University of California has tested this plan is told on page 408 of this issue. The question arises, Can this system be extended to all medical students?

There are 18,000 medical students in the United States. To supply each one with a preceptor would require the services of ten

per cent of the practitioners of the nation. Since 4,500 medical students graduate each year, that number of medical men would be required to act as preceptors if each student spent a month of intensive preceptor work in his course.

If the preceptor system is of great value, the physicians of the country will find a way to make it available to the medical student.

THROWING SAND IN THE PEOPLE'S EYES

When will the people realize the altruistic purpose of physicians in promoting a practice of medicine act?

They will probably continue to believe the get-well-quick fakers as long as they believe the get-rich-quick talkers, and they will ascribe selfish motives to doctors just so long as they call the directors of Savings Banks selfish.

A four-page pamphlet attacking the doctors, that has been widely distributed from the news-stands, reads like a soap-box orator's attack on bank presidents. The keynote of the attack is this quotation:

"If the medical trust is allowed to continue its law-making progress, practically every right possessed by the citizens of this country in connection with the physical care of the body will be taken from them."

No bill that was ever sponsored by physicians ever interfered with the inalienable right of any American citizen to seek healing and comfort

from whatever source of healing he chooses.

No bill was ever passed that forbade any man from investing his savings in wild-cat oil stock or other get-rich-quick scheme, and no man was ever arrested for investing his own money in such a scheme. But many a man has been justly arrested and punished for holding himself out as being able to produce enormous dividends for gullible investors.

No man can ever be arrested for confiding his health and life with any one—doctor or faker—he may choose. Doctors wish to prevent unqualified persons from holding themselves out as being able to produce dividends of health by means of their fake stocks of ignorant manipulations.

The proposed Practice of Medicine law would classify get-well-quick promoters with get-rich-quick fakers.

Those who conjure up the ogre of loss of personal independence are merely throwing sand in the eyes of the people.

COOPERATION OR PARTICIPATION

The word "cooperation" is used so frequently in discussions of public health work that its meaning has become almost trite and formal. It is derived from two Latin words, *co*, together, and *operari*, to work. is thus a tendency toward the development of two opposing meanings of the word "cooperate." This change of meaning is nothing new or strange in the development of the language. The word "slave" is Russian, and formerly meant a free man. But when the mass of the people became vassals to the overlords, the word took on its present meaning of servitude.

The word "participation" more exactly expresses the physician's point of view of harmony of action among the trinity of workers in public health. It comes from two Latin terms, *pars*—part, and *capere*—to take,—therefore, to take part. Physicians are ready to take their part in any phase of public health work. Their peculiar field is technical work for which they alone are qualified, both legally and scientifically. Their relation to other groups in anti-tuberculosis movements, anti-diphtheria campaigns, and similar activities is expressed by the word "participation" more happily than by the word "cooperation."

iodine treatment which may act injuriously from the start. Iodine is and remains, for these reasons, a two edged sword in the conservative treatment of hyperthyreoses (Th Kocher). Attempts at conservative treatment should be made only under exact control of the basal metabolism, for the pulse and weight alone do not give us satisfactory information as to the course of the malady. The author gives an exhaustive bibliography on the subject of the iodine treatment of exophthalmic goitre and quotes very freely from American authors, as Cattel, Sturgis, Mason, Starr, Read, Jackson, Plummer, Boothby, Segall, Walcott, Means, Porter, Richardson and others.

The Treatment of Celiac Disease—This affection, variously known as intestinal infantilism of Herter, pancreatic insufficiency, acholia, and severe chronic indigestion, is defined by Philip S. Potter (*Archives of Pediatrics*, February, 1926, vol. 2) as a vice of nutrition without serious pathological changes, occurring in artificially fed children of early age, characterized by the inability to utilize properly the fats and carbohydrates, by arrested growth, distended abdomen, attacks of recurrent diarrhea with large, ill-smelling, pale, loose, porridgy stools. Before assuming the care of these children it is absolutely necessary to obtain the full cooperation of the parents in all respects and to have them understand that successful treatment is a long tedious process. All clinicians emphasize the need of a high protein diet, a low carbohydrate and a low fat diet, but one containing two or three times as many calories as the normal child needs. During the first stage the diet consists of protein milk alone. Lactic acid milk has an advantage over protein milk in that it has been found that with protein milk the stools remain foul, which is not the case with lactic acid milk, moreover, relapses are more frequent with protein milk. Marriott recommends a quart of skimmed lactic acid milk to which has been added the unwashed curds of two or three quarts of skimmed milk and 7% corn syrup. If there is pronounced emaciation, persistent diarrhea reduced turgor, or signs of tetany, a quart of sterile Ringer's solution may be used in place of the plain water in the preparation of the food, or four or more ounces sweetened with saccharin may be given twice daily for several weeks. In the second stage protein milk feeding is supplemented with curds of buttermilk, skimmed milk, scraped lean beef, white meat of chicken, casein biscuits, tongue, and eggs, the quantity being increased gradually. As auxiliaries, cod liver oil, orange juice, powdered spinach, one to three teaspoonfuls, and syrup of iodide of iron are gradually included. The casein biscuits are made from a starch-free diabetic flour

(15 level tablespoonfuls), egg (1), bacon fat (2 level tablespoonfuls), and water (3 tablespoonfuls). Of these the average child can take five or six a day. In the third stage, carbohydrates are added, between 60 and 65 calories per pound weight, at first dextrinized flours, zwieback, and toasted white bread are added cautiously, but never during the first six weeks of treatment. To overcome the limitation in the use of carbohydrates the pulp of very ripe bananas may be used, the amount being gradually increased to four to eight per day. The day of drugs for the most part is doubtful. Bile salts in the form of sodium taurocholate and glycocholate, one grain each, may be given for the stimulation of bile secretion and the encouragement of fat splitting. Bismuth and soda and aromatic chalk powder may be given for looseness of the stools. Iron is used for the anemia. Intestinal disinfectants are probably not needed when lactic acid milk is used.

Yeast in the Treatment and Prevention of Pellagra—Cosette Faust-Newton, writing in the *Southern Medical Journal* for March, 1926 (xix, 3), adduces evidence, gathered over more than a hundred years, which plainly and unmistakably points to the dietary factor as being the most essential one in the treatment of pellagra. He believes that the evidence points directly to a lack of either vitamin B or an unknown vitamin (Goldberger's P P), or possibly both, as the primary etiological cause of the disease. The diet of pellagrins is almost always lacking in vitamin B, whereas other inadequate factors vary. The tissue changes in pellagra are similar to those of other acknowledged avitaminoses (beriberi, scurvy, Barlow's disease, etc.). Striking success is reported when yeast vitamin B treatment is instituted, as advocated by Goldberger, whose so-called P P (pellagra-preventive factor) seems to be present only in association with water-soluble B. Goldberger gave from 15 to 30 grams (one-half to one ounce), or roughly, two level teaspoonfuls, three to six times a day, using a commercial preparation of dried brewer's yeast, and he supplemented this with a varied diet. The beneficial effects of this treatment have repeatedly been recognized as early as the end of the second or third day after the beginning of the treatment. Dr. Pratt Cheek, of Gamville, Georgia, has used about one hundred pounds of the preparation employed by Goldberger in the last six months and the results, he says, have been highly satisfactory. The effect is noticeable within ten days. The results obtained by those who have used this treatment, the author holds, fully justify Goldberger's claim that brewer's yeast is a specific for pellagra, and he believes it should be generally recognized as such.

MEDICAL PROGRESS

Excretion of Alcohol in the Urine as a Guide to Alcoholic Intoxication—H W Southgate and Godfrey Carter (*British Medical Journal*, March 13, 1926, 1, 3402) give evidence proving the inadequacy of present-day methods of estimating alcoholic intoxication, particularly that of the motorist, who, while showing no signs of gross intoxication, may yet be unfit through alcohol to be in charge of a car. They show that there is a direct relationship between the alcohol consumed and the alcohol in the blood when the alcohol is taken by the same individual under the same conditions. After drinking 144 cc of whisky containing alcohol in a dilution of 20 per cent, the mean ratio of alcohol in the urine to alcohol in the blood one hour after drinking the alcohol is 1.35. This figure is fairly constant. If two solutions, say of 5 and 20 per cent strength are drunk, the alcohol concentration will rise more rapidly and to a higher point in the case of the stronger solution. For instance, after 1,920 cc of beer containing 5 per cent alcohol, 1,200 cc of an 8 per cent aqueous solution of alcohol, and 235 cc of whisky diluted with an equal volume of soda water, thus forming a 20 per cent solution (96 cc alcohol being taken in each instance) the maximum alcohol concentration in the blood rose with increasing concentration of the alcohol drunk. It was also found that diminishing the rate of drinking delayed the accumulation of alcohol in the blood. For instance, drinking beer of 5 per cent strength to bring about real intoxication in any case must be a slow process, because of the large volume that must be imbibed to supply the necessary amount of alcohol. The amount of alcohol in beer that will take a normal man two hours to drink will be drunk in five minutes in the form of whisky. Thus the maximum point of concentration will be lowered when the more dilute beverage is drunk. All food tends to depress the rate of absorption of alcohol from the stomach and intestines and thereby lower the alcoholic concentration of the blood, but some have such a potent action in depressing blood alcohol as to be almost specific. Among these foods bread and milk stand out preëminently. Roughly, the bigger the man the lower will be the concentration of alcohol in the blood produced by a definite amount of alcohol when all other conditions are constant, but this does not seem always to be true. In forensic cases it is obviously not practicable to take a blood specimen and is unnecessary, since the concentration of the alcohol in the urine is proportional to that of the blood, and a fairly constant ratio holds which makes it possible to

deduce one ratio from the other. The problem is to estimate the blood alcohol concentration at the time of arrest. The time of arrest is always noted by the officer. On arrival at the police station the defendant is requested to empty his bladder completely. This specimen gives only the mean alcohol over a previous period of unknown duration, but even this figure is of value. The important sample is the next one, taken, for example at the end of fifteen minutes. This sample will give the mean concentration for the interval or the actual concentration at seven minutes from the time when the bladder was evacuated. If the figure 1.35 be taken as the ratio of urine alcohol to blood alcohol, the blood alcohol at this seven minute interval can be calculated. Knowing this figure and the time interval between the arrest and the emptying of the bladder, the blood alcohol at the time of arrest is calculated from the fact that alcohol concentration in the blood falls at the rate of about 12 mg per hour per 100 grams of blood. It is possible by this means to obtain a close approximation of the blood alcohol concentration of a person at the time of arrest, and therefore of the degree of alcoholic intoxication.

The Iodine Treatment of Hyperthyroidism.—Merke of the surgical clinic of Basle University sums up an exhaustive article in the *Schweizerische medizinische Wochenschrift* of January 30, 1926, on this subject as follows. In the majority of cases Lugol's solution exerts a striking initial action on the hyperthyroidism, affecting favorably the nervous and gastroenteric symptoms, the pulse, and the basal metabolism. The good results which the author terms the "iodine remission," do not depend to any marked extent on the size of the dose. The optimum of improvement is reached after about 8 days of iodine treatment but this favorable action is only transitory and after suspension of the remedy the patient becomes notably worse. A short and intensive treatment with iodine is a very valuable auxiliary for the operative treatment of the hyperthyroidism and in the iodine remission the operative risk is lessened and the plan of the intervention can be abbreviated. If the hyperthyroid patient has received iodine, then within a short time the amount of thyroid tissue can be reduced by operation but further remissions are not to be expected and the more thyroid tissue is left behind the more strongly the symptoms of Graves' disease reappear when the iodine treatment is interrupted. In rare cases of hyperthyroidism we miss the good initial effects of the

ected with one pole of the high frequency machine, the other pole being connected with the autocondensation chair in which the patient sits, enough current is used to cause profuse perspiration at the end of 20 minutes. Finally the blue pencil static brush discharge is used on the affected joint for 20 minutes. In bursitis diathermy is used directly through the bursa, 500 to 800 ma, three times a week. Indirect diathermy is a very safe method and is capable of causing absorption of calcareous deposits and of curing severe and chronic cases in three months. The Committee regrets the prominence given to other types of electrotherapeutic apparatus which has caused neglect of the static machine. There is no other apparatus which can approach the static machine in its power to remove infiltration, induration, and muscle spasm, and to improve circulation and deep tissue massage in and about diseased joints.

Congenital Dislocation of the Hip—After discussing the creditable theories of pathogenesis of congenital dislocation of the hip, Vittorio Putti (*Surgery, Gynecology and Obstetrics*, April, 1926, xlii, 4) emphasizes the importance of recognizing the dislocation as early as possible, even before the child has begun to walk. It is necessary therefore to appreciate symptoms that are not generally known or to which no importance is given. These symptoms are summarized thus. If the dislocation is unilateral, the cutaneous creases of the thigh, so evident in the infant, are no longer symmetrical. On the dislocated side they are proximally displaced, the inguinal and gluteal plates are deeper and longer than on the normal side. The outline of the dislocated hip is more prominent. The luxated hip has a tendency toward external dislocation. Abduction is slightly diminished. Shortening is nearly always minimal, but appreciable to the skilled eye. If the dislocation is bilateral, the pelvis appears enlarged because of the projection of the trochanters, the buttocks are flattened and the limbs cannot be normally abducted. Putti is absolutely convinced that early operation will bring a decided improvement in results. In the treatment of dislocation, he follows the classical method of Paci. For immobilization he follows in a general way the methods of Lorenz. Differing from what is commonly done in America, he divides the immobilization period into two stages. In the first stage the limb is held in the classical first position of Lorenz for three months, during the second stage, lasting from two to three months, the limb is immobilized in a minor degree of right angle abduction and in internal rotation. The open method should be used only in those cases in which the reduction cannot be ob-

tained by the ordinary method, and this occurs in about 5 per cent of the cases. If symptoms of traumatic arthritis appear before the fifteenth year, open operation is indicated. In four cases Putti has performed a real arthroplasty of the hip, modeling in a suitable manner the femoral epiphysis, deepening with an electric drill the cotyloid cavity, and interposing a flap of fascia lata. Among the palliative methods which can suitably be employed is the so-called bifurcation operation of Lorenz, namely an intervention which places the stump of the diaphysis instead of the femoral head in the acetabular cavity. On a basis of 1,879 cases with 2,556 reductions, Putti claims success in 90 per cent of single dislocations and improvement in 65 per cent of bilateral cases.

Paroxysmal Excitability of the Vagosympathetic—Mauriac and Husson, after relating briefly cases of the syndrome in question, sum up the symptomatology as follows (*Le Bulletin Medical*, March 17 and 20, 1926). The patients are usually nervous, dyspeptic, air swallowers, with hepatic insufficiency, enterocolitis, etc. Usually after eating, but at times following nervous excitement, there is a lively flushing of the face and neck with a sensation of heat and turgor, as if the blood-vessels would burst, and of palpitation of the heart. The patient feels ill and is made worse by the notice of those about him. But although he fears a stroke of apoplexy his blood pressure will be found to be normal and even at times subnormal. These crises last an hour or two and there may be several a week and even one daily, but the tendency is for the attacks to subside spontaneously after a short term. In some cases in which the patient develops sitophobia, dreading to eat lest he brings on the spells, he naturally becomes emaciated and weak, with an irritable heart. Search into the literature, limited to French authorities, appears to show that in prescientific days such attacks were common under the name of the vapors or hypochondria, but later the syndrome drops out of sight. Recently it has been described under various names and the authors give Ramond credit for recognition of the essential features in 1918. Others have described "vasomotor crises," "sympathetic syndrome," etc., although without emphasis on the paroxysmal character remarked by Ramond. The diagnosis is easy, for it is only necessary to exclude the mild form of polycythemia, erythrophobia, and a few other unrelated conditions. The authors can only indulge in speculations as to the nature of this syndrome. Treatment is uncertain, for while atropine seems indicated and often relieves there are other cases in which it fails.

Apparent Operative Cures of Cancer of the Stomach—Brodnitz has done but few operations, 21 only, for cancer of the stomach during a long period of years—evidently more than twenty-five. In all cases he used a Billroth II operation, spending only such time in removing lymphnodes as would not much prolong the operation. There was a high operative mortality, five patients succumbing soon after operation—over 25 per cent. Twelve patients died of recurrence all within two years. But four patients still live, apparently free from recurrence, 6, 16, 18 and 25 years after intervention. His percentage of apparent cures, not merely of 3 or 5 years survivors, is about 19. He is, of course, quite unable to explain why the 4 survivors did not share the fate of the 12 with early recurrence. Of diagnosis there could be no question, for every one of the 16 who survived the operation was under able microscopic control. We know through the investigations of Petersen and others that in certain cases cancer cells remain dormant in the lymphatics. Usually these sooner or later become activated, possibly not until many years have gone by, and then we have the delayed recurrence which is so depressing to the prospect of ultimate cures. Hence, it is conceivable that in a few cases the activation does not occur and the patient dies with his cancer still latent. He may be compared to a lawbreaker with suspended sentence. Brodnitz places all of his patients on arsenic, iron, and quinine after operation but does not express any belief in the prophylactic power of these drugs.—*Muenchener medizinische Wochenschrift*, January 22, 1926.

Pylorospasm in the Adult—In the course of an article on pylorospasm in general, limited largely to this affection in the infant, Professor Heile of Wiesbaden makes some statements concerning the same condition in the adult (*Klinische Wochenschrift*, January 29, 1926). Not very much is actually known of it but there are apparently at least two types which are quite distinct. In general, the affection is much less violent, much less acute, in the adult than in the infant. There is the ordinary symptomatic or reflex types as seen especially in gastric ulcer and cholecystitis. The other type may be termed primary, possibly a persistence of an infantile condition. This again is subdivided into forms with a distinct pyloric tumor and a purely functional type, corresponding to the same subdivision in the infant. The author speaks of what he terms latent tumor of the pylorus in which despite the presence of a tumor, there is no spasm for many years, then some unknown factor elicits it. The pure primary form (without tumor) he believes to be common in the adult as compared with the infant, although as already stated the symptoms are not pronounced.

Until recently all pylorospasm was believed by clinicians to be reflex but at present this belief is no longer tenable. Since most of the literature of primary pylorospasm has to do with the infantile form we may visualize the adult primary form as the same affection pursuing a milder, chronic course.

Physical Treatment of Joint Diseases—The report of the Committee on Standardization of Physical Therapeutics, 1925, of which J. W. Travell is chairman (*Physical Therapeutics*, February, 1926, vol. 2) finds in a review of the literature of the past year that in the treatment of joint diseases physical measures are in common use throughout this country. The report sets forth the treatment which the committee considers the most efficient. For acute sprain radiant light and heat rays, of sufficient intensity to cause active hyperemia, are applied for 15 to 20 minutes on the first day, followed by the static sputtering brush discharge for 15 to 20 minutes. On the second day, the static wave current, radiant light and heat, wave brush, in the order named, this treatment is repeated daily. In chronic sprain diathermy is used for 30 minutes, the static wave current for 20 minutes, and then the static spark to the region of the joint, in very chronic cases, r-ray therapy in small doses may be necessary. In strain or sprain of the sacroiliac joint, the sequence is active hyperemia, the static wave current, heavy static sparks, manipulation and correction of the dislocation. In acute synovitis, radiant light and heat are used for 20 minutes, and the static current for 10 minutes. The treatment of acute traumatic arthritis, is like that of acute sprain. In chronic traumatic arthritis, diathermy is used for 20 minutes, the static wave for 15 minutes, then sparks, and passive motion. In acute or chronic toxic arthritis, in addition to the endeavor to clear up the source of infection, the affected joints are treated with the static wave and short static sparks. Where many joints are affected, the static induced current and the static resonator effluve are most effective. In chronic septic arthritis the source and type of the infection should be considered, and locally diathermy with massage and passive motion should be used. In gonococcic arthritis, in addition to all well recognized methods, local treatment is applied to the seminal vesicles with the static vacuum tube of high vacuum from the negative pole for 20 minutes, or very mild diathermy, and diathermy also to the affected joint. In tuberculous arthritis sunlight or ultraviolet light is applied locally and generally, and the r-rays locally in small quantity, always below the skin dosage. In gouty arthritis, general diathermy should be employed with both feet on a metal plate con-

perience is absolutely necessary, skill and aptitude are of high importance, but over and above all this the real basis and the essential foundation for professional confidence and attainment is character!

Character can be felt and perceived rather than defined. We know whom we can trust. The professional man must be worthy of implicit trust. No matter what his knowledge, his training, his experience or his skill, if he be not trustworthy, if he lacks the real essentials of character, he is a menace rather than a minister to the human race.

Even in commercial pursuits character is increasingly recognized as a primary essential to successful attainment.

No higher or more competent tribute has been paid the medical profession in recent years than that which was vouchsafed the other day by one of the leading jurists of this city. To the *Medical Week*, the weekly publication of the New York County Medical Society, we are indebted for this fine judicial appreciation uttered by Chief Magistrate William McAdoo.

"The medical profession," this trusted public servant said, "is among the noblest, and to me it is a sacred one. It is in the forefront of civilization, especially in dealing with preventable diseases. It has made more advances in dealing with human suffering and preventable death than all other agencies. If ever

there is a roster of secular saints, the medical profession will crowd the ranks."

Speaking of our laws, which are designed to protect a credulous public against the deceits and the unprincipled knavery of dishonorable and unlicensed charlatans, and to safeguard and protect the honorable practitioner of medicine, Judge McAdoo further said:

"This State has hedged around this, I might say almost holy and sacred profession, dealing as it does with life and death, protection against quackery of all kinds, until our law in this State really reads that no one can profess to cure or undertake to cure by any means, whether muscular manipulation or the administration of drugs, or what not, without invading, and being guilty under our statutes, of practicing medicine without a license."

Every physician who is ever tempted to deviate from the paths of rectitude, from the high standards of professional honor or the exalted obligations which he has assumed, should pause and reflect upon these things. The writer, as the friend and the adviser of more than ten thousand doctors in this State, is constantly impressed by the uniformity with which medical practitioners follow and adhere to the principles of conduct to which they have sworn allegiance.

"With purity and with holiness I will pass my life and practice my art!"

TONSILLECTOMY—LOCAL ANAESTHESIA—BREAKING OF NEEDLE

The defendant in this action was the attending laryngologist at the clinic of a hospital. The defendant in the performance of his tonsillectomy had removed both tonsils by separation and snare, using a local anaesthesia. While injecting the local anaesthesia into the tonsillar area the patient, in suddenly jerking his head, broke the hypodermic needle and about one and a quarter inches of the needle remained lodged in the tissue beyond the tonsil. Attempts were made with clamps and forceps at that time to extract the needle, but such attempts were unsuccessful. Thereupon the patient was referred to the oral surgeon at the hospital for the removal of the broken needle. After examination of the patient the oral surgeon advised that no attempts be made at that time to remove the needle as it was beyond the capsule of the tonsil. X-rays taken showed the needle at that point. Nothing further was heard from this patient for some period of time, when the defendant received a telephone call from a physician at another hospital advising the defendant that

arrangements were being made for the removal of the broken needle under a local anaesthesia by external operation. Prior to this operation X-Rays were taken and showed the presence of the needle in the throat. The needle was removed by the second surgeon without any untoward results. At no time did the patient suffer any infection by reason of the presence of the needle or by virtue of the operation.

After the needle had been removed an action of alleged malpractice was instituted against this defendant, charging him with negligence in the performance of his operation in causing the needle to break and remain in the plaintiff's throat.

During the pendency of the action the defendant physician died. The action being one of alleged malpractice the same abated with the death of the defendant. This is a type of action which dies either with the death of the plaintiff or the death of the defendant, and does not survive to the administrators of either party.

LEGAL

By LLOYD PAUL STRYKER, Esq
Counsel, Medical Society of the State of New York

CHARACTER THE REAL BASIS OF PROFESSIONAL CONFIDENCE

"I will follow the system of regimen which according to my ability and judgment I consider for the benefit of my patients and abstain from whatever is deleterious and mischievous

With purity and with holiness I will pass my life and practice my art

Into whatever houses I enter, I will go into them for the benefit of the sick and will abstain from every voluntary act of mischief and corruption" Thus in the classical language of ancient Greece Hippocrates, the father and the founder of the medical profession, more than four hundred years before the birth of Christ, placed character as the essential basis of professional confidence. These precepts he wrote into the Hippocratic oath—an oath the perennial sanction of which is recognized in the United States now, as it was in the heyday of Hellenic culture.

In this commercial era, when success is so largely measured by monetary standards, the difference between a business and a profession cannot be too often emphasized. In the former, financial reward is the primary and essential aim, in the latter the object and purpose are the service to mankind, and monetary reward is merely the incident which makes it possible for those who have enlisted in a high calling to live and carry on their work.

"Every one on entering the medical profession and thereby becoming entitled to full professional fellowship," so read the Principles of Professional Conduct of the Medical Society of the State of New York, "incurs an obligation to advance the science and art of medicine, to guard and uphold its high standard of honor, to conform to the principles of professional conduct and to comport himself as a gentleman." And further "The medical profession exacts from its members the highest type of character and morals, and to attain such a standard is a duty every physician owes alike to the profession and to the public." And again "Physicians should not only be ever ready to respond to the calls of the sick and the injured, but should be mindful of the high character of their mission and the responsibilities they incur in the discharge of their professional duties." In their ministrations they should never forget that the health and the life of those entrusted to their care depend on skill and attention." And further "Every patient should be treated with attention and consideration and the confidences which physicians receive should be

guarded with the most scrupulous fidelity and honor." And still further "The physician should be a minister of hope and comfort to the sick." And again "It is the duty of physicians to bear their part in sustaining the laws, institutions and burdens of their community, they should co-operate in the preservation and enforcement of sanitary laws and regulations in the interest of public health. Physicians should always recognize poverty as presenting claims for gratuitous services. Every physician should guard and protect the medical profession against the admission of those who are either in moral character or education unfit as professional associates."

These are the recognized canons of professional conduct. They embrace principles to which all legitimate and honorable practitioners of medicine formally subscribe—principles, however, which have a deeper sanction than could be given by any mere formal recognition of their authority. They are the principles of right conduct and of character that are written into the consciences of those who have dedicated their lives to the healing art. The true physician recognizes and adopts these aims without the necessity of referring to any mere printed text which outlines and defines them, just as the true principles of justice are felt and perceived by the honorable advocate, over and above the cold precedents of the law. "The sacred rights of mankind," wrote Alexander Hamilton, "are not to be rummaged for among old parchments or in musty records, no, for they are written as with a sunbeam in the whole volume of human nature by the hand of the Divinity itself, where they can never be obliterated or obscured by mortal power."

The soldier has his manual of court martial, his books of strategy and tactics, his regulations for camp and combat, but over and above these his love of country guides and impels his action, even to the ultimate and final sacrifice. The clergy have their testaments, their books on theology and ethics, but their desire to help and to uplift the human race, as an impelling guide, is written upon the secret tablets of their hearts.

These are some of the reasons why the real lawyer resents hearing his profession referred to as the "law business" and why other professional men object to similar characterizations of the callings they have chosen. Knowledge is essential, training is indispensable, ex-

pursuit of happiness. It will call forth the best that is in one and, if he is a fighter, he will fight until the last barrier has been taken. There is great joy in the victory won in a clean fight."

This student enumerates sixty-four diagnoses of patients which he saw, each of which were made on from one to forty cases. He must have had a busy month packed full of varied experiences. He closes with these impressions:

"Much of the valuable experience that I derived from this unique service cannot be told, as it is only within myself. There is a certain confidence that comes, and a certain ability to act quickly and to think quickly and simply. It teaches one to think of the simple things first, and then, if necessary, refer back to the more remote possibilities. The main thing is to do something quickly and to keep your head. One should tell as much of the truth to his patients as is logical, and always say frankly that you do not know if something stumps you. These are a few ideas gleaned from all the doctors with whom I came in contact."

The second student spent his month in a group clinic conducted in a town of 2,500 people. He also accompanied some of the doctors on their rounds and on their visits to a hospital for paupers. He writes:

"I had heard a lot about group clinics, and the one at Woodland very nearly approaches the ideal. It was really good to see how they all worked together and helped each other. Every case gave to each one something of value. When one is practicing alone he naturally learns some things, but he also is apt to get into a rut, not only with his thinking, but in the way he does things. At the clinic, due to the combined aggressiveness and fine spirit, there is no chance to get into a rut. The clinic has an excellent library and with staff meetings where current literature is discussed, each member covering a certain field. The men are kept in close touch with the doings of the medical world. The men in the clinic are first, honest, and secondly, well trained, and so just knowing them many times overpaid me for all my time and effort."

"I have had for a long time the desire to practice in the country. The month in Woodland makes me more determined and certain that, after graduation, I shall practice in the country."

The third student was fortunate enough to be with a doctor who made it a practice to keep fully written records of his cases. He writes:

"The first lesson, although not previously planned, proved to be perhaps the most valuable one during the month. A young dentist, with office nearby, came into the office with one of his patients and a member of her family to ask Dr. Seawell's opinion concerning the proper method of treating an aching tooth.

The fact developed that the patient had absolutely no confidence in the ability of the dentist to handle the case, and was unwilling to undergo the proposed treatment without first consulting Dr. Seawell, whom she knew did not have the knowledge of dentistry of the other man, but in whom she had the utmost confidence and faith. This lesson brought out the fact, which was daily demonstrated, that a great part of the success of the man in practice lies in having the absolute confidence of the patient. A more timely demonstration for the benefit of a student is difficult to imagine, and its moral will never be forgotten."

He also adds his impressions about the way country doctors use their ingenuity in devising equipments and making diagnoses:

"The man in the general practice of medicine relies upon his eyes and his hands rather than upon instruments, except where they are really needed, for the diagnosis of his cases. In the home the necessity for using one's eyes and hands is shown most clearly. The light is not always of the best, there is no handy 'chariot' from which to procure tongue blades, and it is impossible to resort to instrumental methods such as we are trained to use in the hospital, so that we realize the insistence of our teachers in the hospital wards to use our eyes and our hands (as well as our heads) in the examination of patients. I learned that spoon-handles make satisfactory tongue depressors, that a few well-chosen drugs conveniently carried do just as well as elaborate prescriptions, and many other practical things that can be easily carried out in the home. More than this, however, I learned that if one is honest, kindly to all, tolerant and patient, there is, with his entrance into a home, a sense of relief, which, after all, in many cases is more than 50 per cent of the cure."

"I have seen a doctor enter the home of frightened parents of a sick child at midnight. I have seen him take the temperature, feel the pulse, drop a few cheery words and, without doing another thing, leave the household in perfect confidence that everything was and would continue to be all right. I think I began to understand something of the 'art of medicine' on such occasions, but I know I understood that behind this confidence was the implicit faith in the honesty and straightforwardness of the doctor. In addition to these attributes, or rather to possess them, one must have a knowledge of medicine of such a degree that confidence in one's self is inspired."

The fourth student was paired with student number one in a doctor's office. He wrote the following impressions:

"Besides seeing many cases and methods of treatment, I learned a great deal about the human side of the practice of medicine. By the

OUR NEIGHBORS

PRECEPTORS FOR MEDICAL STUDENTS

The April issue of California and Western Medicine, the official organ of the Medical Societies of the States of California, Nevada and Utah, contains an interesting description of a unique experiment in reviving the old preceptorial system by which medical students were apprenticed to practitioners who taught them the art of medicine or how to deal with people, while the medical school taught them science or how to deal with a disease. Some students have an instinctive knowledge of the way to make a happy approach to a patient, while others who know their science never acquire the art of satisfying patients because that side of the practice of medicine has never been brought to their attention. Medical schools have a way of turning a graduate loose upon the public as soon as he shows a knowledge of the science of medicine, regardless of the tyro's knowledge of the *Art* of practice. The result is like that of turning loose a musical student who knows the theory of the piano, but cannot play a tune. A quack doctor is successful because he knows the psychological art of pleasing his patients.

To give every medical student an opportunity to see how family doctors practice medicine would seem to be a necessary part of his training, as it was a half century ago. But it has remained for Dr. William J. Kerr, the head of the Department of Medicine in the Medical School of the University of California, to demonstrate the method. He chose four senior students and sent them to three general practitioners of medicine and to a small country hospital. The following quotations from their reports reveal their enthusiastic approval of the plan.

The first student spent a month in the office of a public-spirited doctor who was also health officer and was interested in civic affairs. This student wrote:

"One can see that a general practitioner is a busy man. Not only were professional duties attended to, but also municipal duties along public health lines. There were also the noon luncheon clubs to attend and committee meetings of all kinds.

"Dr. Chain, being health officer of the city of Eureka, made calls on smallpox, and other patients with 'reportable' diseases. I also saw the inner workings of a city health laboratory. Every day the city water was tested for colon bacillus, and once a month the milk supply was given a bacteria count. The routine diphtheria cultures were run through every day, and many

other examinations of specimens of all kinds made.

"I also saw the indifference of the average doctor to public health matters. Some even resent interference with their work, even in the enforcement of quarantine.

"The Tuberculosis School was another source of interest and profit to me. In this school they teach the persons who are infected how to live and how to prevent the spread of the disease, as well as help them on the road to recovery. Contacts are taken in and taught the food to eat, the precautions to take, and the routine life they must live in order that the disease will not take a firm root in their bodies.

"To do effective public health work in the small town is not conducive to popularity. The quarantine of a diseased case may gain the enmity of the doctor and the family. The killing of a pet poodle with rabies may incur the enmity of a certain faction in the community. The destruction of a herd of tuberculous cattle brings a decided reaction from the farmers. The life of the public health doctor is a bitter struggle, where enemies are made and very little praise received. One must have the courage of his convictions and have the good of his profession and the welfare of the community at heart.

"These small-town doctors possess that wonderful something that one acquires in mastering the art of medicine. They do not have patients who are seen in the ward or office and then forgotten. All of their patients are their friends. The doctor is vitally interested in them and they have absolute confidence in him. It is an inspiration to see the faith that these people have. They are a simple people, and demand simplicity in return. All the doctors possess that spark of sympathy that kindles in every person a feeling of faith and hope. One realizes that ours is a noble profession and demands high ideals. You are the priest as well as the doctor, and in many of the cases a bit of kind advice goes much further than tons of C. C. pills.

"The picture must not be painted too brilliantly. Unfortunately, one must live. One must have money. There are men in the profession who so devotedly worship at this shrine that they lose their higher ideals. This is often the cause of bitter jealousies and of unprofessional practices. The cream of the jest is that this is merely life. In the lecture hall and classroom we do not realize that outside of the college there is a bitter fight for the preservation of life and the

of sincerity, and knowledge of Dr Kerr's ideals, and strict obedience to them on the part of the preceptor, as well as the student selected, for it would be a tragedy to besmirch the student possessed of the ethics and training of an established and honored university by an association with the physician or surgeon whose position and affluence were the outcome of perfidious methods of pseudo-humanitarianism.

Again, before the departure of the student it should be impressed upon him that he is on his way to be educated in the art particularly, and very much less so in the financial remuneration of the art, and that he must accept the finer principles of the art only when they correlate with his own rules of honorable conduct.

"The preceptor must not see in the presence of the student a possible unqualified assistant for here lies a great danger.

It would seem to me that a well-equipped general practitioner should be assigned to the teaching staff of the university, and should

receive a proper titular position and a chair, subsidiary if you like, on the art of medicine, for by so doing, Dr Kerr's plan would be enhanced, as the student would leave for his month's association with the preceptor equipped to appreciate the art as demonstrated by him.

"A science teaches us to know, an art teaches to do and the doing of a doctor is to cure. Dr Kerr's most praiseworthy and interesting experiment will, I am confident inculcate in the self-reliant and the diffident student alike a courage to cure, the possession of which brings the confidence of the patient which, after all, is the foundation of any medical man's efficiency."

It would seem that an intimate apprenticeship of a month or two, with a general practitioner would be a most valuable asset to a young medical graduate. Possibly, too, it would be to the advantage of the doctor to brush up on his science. The plan has the possibilities of an exchange of equal values between student and preceptor.

COLLEGE OF HEALTH EXAMINATION AND EFFICIENCY RESEARCH

There is how the Oregon State Medical Society is acting on the question of periodic health examination, according to the April issue of *Northwest Medicine*, the organ of the medical societies of the States of Oregon, Washington, Idaho, and Montana.

"In order that approved methods for examination of apparently well persons may be facilitated, it is proposed to select a faculty from the members of the Oregon State Medical Society who have shown themselves competent for making physical examinations in a creditable manner. They will organize a 'College of Health Examination and Efficiency Research' to be known as the C H E E R. They will first qualify by being examined themselves and agreeing to be examined annually. Team work will be used for giving instruction and demonstration examinations before classes and medical societies. A postgraduate course of instruction will be open to all members of the society, provided that they agree to be examined themselves and to take a course of instruction in making thorough examinations.

Particular care will be used in selecting instructors who have demonstrated their ability to do this work well. When a member of the Society has completed one hundred examinations and filed his case records with the college, his application for fellowship will be considered. If the records are approved and the advice given by him is satisfactory, the faculty can then elect him a fellow. It is necessary, however, for every fellow, member and student to go on record, stating he will be examined annually."

"This movement is to be popularized by practical demonstrations before local medical societies. It is of the utmost importance that every physician interested should not only be examined annually himself, but should make every effort to see that the members of his family also use this privilege. We would then be able to demonstrate to the public that we are not only taking our own medicine but are placing ourselves and our families in a position to enjoy longer life and better health."

human side I mean the ability to encourage a patient who has a slow recovery before him, the knowledge of what to say when a diagnosis cannot be established at the first visit so as not to lose the confidence of the family, or tact in giving to the relatives a practically hopeless prognosis without shocking them. Of course, there are no stereotyped formulas for these and many other delicate situations with which a physician has to cope, and, even if there were such formulas, three weeks would not be nearly sufficient time to learn them. But these three weeks under the guidance of the doctor have given me the realization that every patient and every family is a problem of its own, and that the most important thing in the relations between doctor and patient is the sympathetic attitude of the former to the latter. If this spirit of sympathy prevails it will not be very difficult for the doctor to do or to say the right thing, provided he has a reasonable knowledge of human nature that gradually develops with years of experience.

"In still another way have I profited by this experience. There is something lacking in the life of a medical student, perhaps it is lack of time or the fact that in teaching hospitals the patients are cared for by the staff, and the student does not have the personal contact with them which would be most valuable for him. Contact with the doctor and his humanitarian point of view, which makes him see the situation through the patient's eyes, has helped me to see this fault in myself.

"In my opinion, this elective course in Practical Therapeutics and the Art of Medicine is a unique opportunity for the medical student, and I would not have missed it for a great deal. It also seems to me that what has been done this year at the University of California Medical School should be communicated by some appropriate channel to other medical schools.

"In conclusion, I want to say that I think the value of an elective course such as this would be still enhanced if it were offered after completion of the interne year. There are several arguments in favor of this. In the first place, the young doctor would be in a position to get more out of it than the senior student. In the second place, more time could be devoted to the course, say from six weeks to three months, depending on mutual agreement, and, last but not least, the physician in charge would be able to delegate the young doctor to do a part of his routine practice and thus receive something in return for the time and effort required for teaching."

Dr Ray Lyman Wilbur, President of Stanford University and Past President of the American Medical Association, comments on the experiment

"It is an inspiration for any medical student to come in actual contact with the ordinary life of the practising physician. I am very much pleased with Dr Kerr's experiment and with the results. I think it offers a method of revival of some of the most useful elements in the apprenticeship system. While it may be troublesome, it seems to me that it has advantages, both for the practitioner and for the student. Any wide-awake well-trained medical student can contribute a great deal by spending a month with a man practicing in the country. He is not entirely on the receiving end. The doctor gets considerable assistance."

Dr Fred R Fairchild of the group clinic to which one of the students was assigned, writes

"It is accepted that our young men and women are graduated with a high degree of technical knowledge. It is almost as generally recognized that they are graduated with a minimum appreciation of the true art of the physician.

"Scientific training is not a substitute for a lack of sympathy and understanding. An ability to view disease from the patient's standpoint is the fundamental principle upon which the art of the practice of medicine is based. A high degree of specialization tends toward commercialism and a cold-blooded, scientific approach. A disease is viewed as an interesting scientific problem, not as a disaster that has overtaken a human being.

"The plan by which the student is given an intimate association with a man in general practice who knows his patient and understands his economic problems, as well as his physical ills, will give to him a new conception of the true physician. And only by such association can the student come to have any idea of the value of this intimate relation.

"The student will approach such an experience with enthusiasm and with not a little egoism. He will feel that he is better trained—and usually he is—scientifically, than the man to whom he goes. He will confidently match his theoretical, scientific knowledge against the years of experience and the practical horse-sense of his preceptor, and he will return to his duties at college a wiser and a humbler lad.

"Dr Kerr should have our unqualified support. This little beginning, carried to its logical conclusions bids fair to restore to our profession something of the wonderful spirit which the laboratory has crowded out."

Dr J Wilson Shiels comments on the experiment as follows

"The success of Kerr's plan depends absolutely upon the most careful selection of the preceptor, and this selection should not be governed by any wealth other than a wealth

own children for a more eminent service to the world relatively than the members of any other profession. Whatever may be said for the cele-

briety of the clergy, there is something to be said for a system whose ministers contribute so largely to a public good through their sons."

SONS OF PHYSICIANS

It is interesting to compare the children of ministers with those of physicians. This has been done by Dr William Browning of Brooklyn, in a book of 225 pages entitled "Medical Heredity." On page 175, Dr Browning quotes "Who's Who in America" for 1910-11, and shows that out of 16,027 persons listed, 846 were sons of physicians. This makes the percentage five and a quarter—about half that of the sons of ministers. Three persons out of the sixty-two in the "Hall of Fame" of the New York University were children of physicians—a percentage of a little over five.

There is an opportunity for someone statistically inclined to study the sons of the present generation of physicians of New York State and the Nation.

How many sons of physicians, or are studying medicine?

How many sons have entered the profession because of the quiet example of their father's love for medical work?

How many sons have not considered a medical career because their fathers said "I don't want any son of mine to be a doctor?"

FAITH HEALING

Dr S. Parkes Cadman, pastor of the Central Congregational Church of Brooklyn, N. Y., frequently expresses his views regarding the relation of science to religion. The *Herald-Tribune* of April 16 contains the following question:

"You have quoted in connection with the cleansing of the lepers one of Jesus' sayings: 'He that believeth on me, the works that I do shall he do also, and greater works than these shall he do, because I go unto my Father.'"

"We are taught that the Bible is a book of truth, and, such being the case, can we not take these words literally and hope for physical relief if we have the needed faith?"

Dr Cadman's reply was as follows:

"When Jesus said to the disciples, 'The works that I do shall he do also,' He did not add the clause, 'in the same way that I do them.' Twentieth century Christians believe in Christ and also obey those laws of life and health which were not clearly understood in New Testament times."

"Modern scientific methods of attacking disease have triumphed over it in such wholesale

fashion as to fulfill this great saying of Christ:

"Think of the banishing of yellow fever from South American ports and the checking of Asiatic cholera in the Philippines as instances of the overwhelming defeat of misery and death which our age has witnessed!"

"The New Testament nowhere promises universal immunity from bodily sickness and suffering. Its actual writers were tortured, flayed, burned and crucified. Its Lord hung on a cross wet with His life blood. The 'greater works' of which He spoke in St. John's Gospel (xiv 12) are by no means confined to marvels of physical healing. On the contrary, they cover the entire scope of a new dispensation of which Christ is the central figure and the Everlasting Father of its program and power."

"Survey, I beg you, the splendid unfoldings of that dispensation in history and experience for the past twenty centuries. Then you will be the better prepared in body and soul to take advantage of physical and spiritual aids for your own relief."

THE DAILY PRESS

BURBANK AND MEDICINE

The recent death of Luther Burbank has focused attention on evolution of which he, like his great predecessor, Mendel, was a practical exponent. As the Monk, Mendel discovered and formulated the laws of heredity, so Luther Burbank, a half century later, applied those laws in an extremely practical way in the breeding of plants. Other men had improved the breeds of both animals and plants by the selection of the best parent stocks, but Burbank experimented on a scale more elaborate than ever before. He started with pedigreed seeds, accurately cross-fertilized the flowers on the developing plants, and worked only with the very few plants that showed the qualities which he desired.

An editorial in the New York *Herald-Tribune* of April 12 comments on his achievements as follows:

"The work of the great plant experimenter was of immense practical value. His improvement of staple foods alone made him a permanent world benefactor. It was his good fortune that his achievements were of a type to capture imagination, and his unselfish, lovable charac-

ter seemed to all quite in keeping with the gentle art which he pursued with such consummate skill.

"Burbank deprecated the notion that he was a creator. He gave superlatively intelligent direction to plant breeding. His experimental gardens were, in his view, a laboratory of evolution. Certainly there has never been more astonishing manipulations of hereditary traits than he achieved. He had no doubt that the same kind of magic could evolve an aristocracy of the human race. He would not have been averse, perhaps, to trying that experiment. 'But they wouldn't let me,' he said."

Luther Burbank's work led him naturally into theological speculations to which only casual references were made in the daily press. To him the great controlling factor in all forms of life, including the human, was hereditary rather than environment, predestination rather than conversion, and faith rather than works. It is no wonder that he supported faith healing, even though he was reported to hold atheistic views.

SONS OF MINISTERS OF THE GOSPEL

A favorite example quoted by the opponents of the theory of heredity is that of erring sons of ministers of the Gospel. The *Herald-Tribune* of April first has a lengthy editorial on that subject whose occasion was a meeting of the Sons of Methodist Ministers. The editorial took the year book, "Who's Who in America" for 1922-1923 as a standard measure of prominence, for in that year all persons who were listed gave the occupations of their fathers. The editorial says:

"Eleven and one-tenth per cent of those recorded had a clergyman for a father. Besides, a considerable number reported that the father was a 'farmer and preacher,' etc."

The *Tribune* then analyzes these figures and takes the census figures for 1870, which was the census nearest the year of birth of the prominent men listed in the 1922 year book, and shows that the Protestant clergymen in that year numbered four-tenths of one per cent of all the men living at that time. Making comparison with men in other occupations, the editor says:

"In proportion to the population clergymen fathered fully twenty-eight times the average number of notables—as notability is reckoned by

'Who's Who.' Another way of putting it is that the clergymen of 1870 contributed in proportion to their numbers about 2,400 times as many eminent persons, according to these standards, as did unskilled laborers, thirty-five times as many as did farmers, four times as many as business men, and over twice as many as the average of other professional men."

The editor is inclined to the belief that the sons of ministers acquire fame because of their early environment rather than heredity, but he says:

"But even a half-century ago the ministry invited to a greater extent relatively the more brilliant minds, and it is to be assumed that heredity has also entered into the advantage that men had who were born the sons of clergymen in that period, and back of it to the first Colonial days, when the minister had usually the most respected place in every community.

"The ministers are at a disadvantage when their salaries are compared with those of other vocations, even teachers, yet by thrift and sacrifice they have managed not only to continue in their high profession, but also to prepare their

The book should be read by every medical man and should find a conspicuous place on the table of his waiting-room

F. B. DOYLE

SOCIAL PSYCHOLOGY By KNIGHT DUNLAP Octavo of 261 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$4.00

If you are looking for an interesting book, that is brimful of information, on Social Psychology, look no farther. At last, one has been written that covers the field in an intelligent manner. The unconscious mind is cast into the limbo, and human traits are discussed as they exist and not through symbols. The author is wise enough to know that most people are quite conscious of their sexuality, and that the dream world does not have to be invaded to find out the real person. The chapter on marriage is peculiarly interesting, and, if read understandingly, would be of far greater help to married persons than most of the books on the subject that we have read. The other chapters are of interest but less so than the one on marriage. This institution is being reviewed from many angles to-day. The author discusses it historically as well as psychologically, so that the reader has a broad viewpoint, if he wishes to further investigate the subject. The comparison of men with women in so many different ways we imagine, will detract from the popularity of the book, as this feature will be irritating to some persons and more especially to women. Be that as it may, we can recommend this book as one of prime importance both to physicians and people generally.

J. ARTHUR BUCHANAN

THE EARLY DIAGNOSIS OF THE ACUTE ABDOMEN By ZACHARY COPE, B.A., M.D., M.S., Lond., F.R.C.S. Eng. Third Edition Octavo of 233 pages with 28 illustrations London Humphrey Milford, New York Oxford University Press, 1925 Cloth, \$3.80 (Oxford Medical Publications)

A comparatively small book, of some 200 pages, it contains a vast amount of information on a subject of paramount interest to every practitioner.

The author dwells particularly on the importance of early diagnosis. He points out the essential characteristic features associated with each particular acute disease of certain abdominal viscera. These when analyzed and properly interpreted, indicate the diagnosis.

Attention is called to certain acute thoracic conditions, the onset of which frequently simulates an acute abdomen. In these cases, a hasty diagnosis and a rash surgical attack often leads to disaster.

One must read this book to appreciate it.

HERMAN SHANN

THE NURSING OF EYE CASES By LOUISE KINGHAM S.R.N. 16mo of 16 pages London, Humphrey Milford, New York, Oxford University Press, 1925 Paper, 30c.

A most estimable little folder written ostensibly for the nurse "to give" her 'some notion of the relative gravity of accidents to the eye.' The reviewer feels that he has gained considerably by a perusal of this fifteen-page outline, that any Board of Directors would be well repaid if they presented each Intern, Nurse and Orderly with a copy of it. It certainly is a very definite and impressive method of insuring more intelligent co-operation.

J. N. EVANS

ARTIFICIAL SUNLIGHT AND ITS THERAPEUTIC USES By FRANCIS HOWARD HUMPHRIES M.D. (Brux.), F.R.C.P. (Edin.), M.R.C.S. (Eng.) L.R.C.P. (Lond.), L.M. (Rot., Dublin), D.M.R. and E. (Cantab.) Second Edition Octavo of 201 pages with 11 illustrations.

London Humphrey Milford, New York Oxford University Press, 1925 Cloth, \$2.75 (Oxford Medical Publications)

In the last few years the growing interest in the newer physical agents has brought forth many books concerning them, their apparatus and the technique of their application. In some instances the claims put forward by the authors encourage one to suspect, at least, a hyper enthusiasm for their subject. In this new book Doctor Humphries has given us a fair statement of the facts. The theory is thoroughly discussed, the apparatus is described in detail and the indications, proper dosage and technique are so well handled that the work might well be called a handbook or manual, of the subject.

The chapter on the use of artificial sunlight in the treatment of skin diseases is very interesting and instructive. The author claims, and we think rightly so, superiority for this agent in the treatment of alopecia areata. In its use outside of dermatology we have had no experience and of course are not qualified to speak, but, judging from his statements made concerning its uses in our field, we believe that the book will prove a valuable addition to any medical man's library.

The illustrations are well executed and the whole book from a physical standpoint is in the usual splendid style of the Oxford University Press.

NATHAN T. BEERS

SOME FUNDAMENTAL CONSIDERATIONS IN THE TREATMENT OF EMPYEMA THORACIS By EMMETT A. GRAHAM, A.B. M.D., Professor Surgery Washington University School Medicine. Illustrated, C. V. Mosby Co., 1925 Price, \$2.50

This essay was awarded the Samuel D. Gross Prize of the Philadelphia Academy of Surgery in 1920.

The essential points of the principles of treatment advocated by the author are (1) Careful avoidance of open pneumothorax in the acute stage, (2) The prevention of a chronic empyema by the rapid sterilization and obliteration of the infected cavity, and (3) Careful attention to the nutrition of the patient.

The chapter on Pathology is very complete and descriptive, and an effort is made to justify the enumeration of the above principles rather than to go into an exhaustive discussion of the many details involved in the surgical treatment.

The Addendum answers the criticisms of some of the theoretical aspects of the treatment of empyema, as it was described in the original essay. A Bibliography is added which contains some references as recent as 1924. This is a valuable contribution to the literature on this subject by reason of the completeness of the study.

J. R.

CLINICAL LABORATORY MEDICINE. A Text-Book of Clinical Laboratory Diagnostic and Therapeutic Procedures By HENRY M. FEINBLATT, M.D., and ARNOLD H. EGGERTH, A.B., A.M. Octavo of 424 pages with illustrations New York, William Wood and Company, 1925 Cloth, \$5.00

This book includes a description of the methods in clinical pathology which have been found most satisfactory in the hands of the authors, together with special chapters on such subjects as hydrogen ion concentration, basal metabolism, blood transfusions, the use of convalescent serum in measles, the Shick test and the Dick test together with active and passive immunization to scarlet fever and diphtheria. Perhaps the chief value of the book lies in the interpretation of the various chemical findings, which is based upon elaborate studies of both the clinical and analytical factors in a very large series of patients. The result of these studies have been published in a series of papers by Feinblatt within the past few years, which are familiar to students of the current literature. It is satisfactory to have them consolidated as they furnish an authoritative basis for judging the significance of these factors.

T. H.

BOOK REVIEWS

TEXT-BOOK OF NERVOUS DISEASES FOR THE USE OF STUDENTS AND PRACTITIONERS OF MEDICINE. By CHARLES L. DANA, A.M., M.D., LL.D., Professor Nervous Diseases Cornell University Medical College, Consulting Physician Bellevue Hospital Tenth Edition Two hundred and sixty-two illustrations, four plates in black and color William Wood and Co., 1925 Price, \$7.00

The development and progress of the science of neurology might well be of interest to the world in general. Because of the fact that the neurologist comes in contact with every vital problem in life, its cause and effect, his efforts and accomplishments unquestionably bear upon the welfare of the human race. This text-book contains the study of the diseases of the nervous system, there is a chapter on medical psychology, the study of which is absolutely essential for and fundamental to the comprehension of nervous diseases. Of great interest is a chapter on the history of neurology, proving this science to be by no means young. As far back as the very beginnings of civilization was there knowledge of "neuroses" and research work along those lines. This chapter by Fielding H. Garrison, A.B., M.D., is most fascinating and profitably educating. In this edition the author has brought the text up-to-date and has added new chapters on preventive neurology and Epidemic Encephalitis. We believe this to be an excellent book for the student, it is complete in subject matter rendered in such a way as to be easily grasped by the reader. F. C. E.

WILLIAM CADOGAN (His Essay on Gout). By JOHN R. HARRAH, M.D. Professor Diseases of Children, University Maryland Paul B. Hoeber, New York, 1925 Price, \$1.50

This is indeed a very entertaining book from the standpoint of medical history. The poem in the last part of the book is very good.

The subject is well gone over and it shows that there is little in regard to treatment, that has changed from the eighteenth century up to the present time. One can get a great deal of pleasure as well as instruction in reading this book.

KENNETH MACINNES

OPERATING ROOM PROCEDURE FOR NURSES AND INTERNS By HENRY C. FALK, M.D., with foreword by EUGENE H. POOL, M.D. With 275 illustrations G. P. Putnam's Sons, New York, 1925 Price, \$2.50

This volume contains a description of the desiderata for the ideal operating room, personnel, apparel. The method of making supplies, dressings, drains, system of keeping supplies, the preparation of the patient, care and sterilization of instruments, hands, "setting up" of the operating room, and a detailed discussion of necessities for each individual operation are some of the topics treated. H. K.

PUBLIC HEALTH IN THE UNITED STATES An Outline with Statistical Data. By HARRY H. MOORE. Octavo of 557 pages, with illustrations. New York and London, Harper and Brothers, 1923. Cloth, \$4.00 (Harper's Public Health Series)

This volume is an illuminating record of the public health activities in the United States. It especially demonstrates the practicability of this work. The chapter on "Unconquered Enemies" is not only extremely interesting but should inspire a great many of us to strive to overcome these sources of danger. The work covers all angles of the sanitary situation of the present age. J. J. W.

A TEXT-BOOK OF PATHOLOGY, with a Final Section on Post-Mortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By FRANCIS DELAFIELD, Sometime Professor Practice of Medicine, College of Physicians and Surgeons, New York, and A. MITCHELL PRUDEN, M.D., LL.D., Sometime Professor of Pathology, College of Physicians and Surgeons, New York. Thirteenth Edition. Revised by FRANCIS CARTER WOOD, M.D., Director Pathological Department, St. John's Hospital, and Institute of Cancer Research, Columbia University, New York. Eighteen full-page plates and eight hundred and ten illustrations, text in black and colors. William Wood and Co., New York, 1925 Price, \$10.00

The subject of pathology is very well presented by authors of recognized standing in this field. The book is divided into three parts. First, general pathology which treats of the structural changes that occur in the body tissues during disease irrespective of any special location. The second part takes up special pathology, which consists of the structural changes that occur in the different organs during disease. In the third part the subject of post-mortem examinations is taken up. In this section there is a detailed description of the methods to be pursued in making a post-mortem examination, whereby the different lesions in the organs are noted and correlated. As a whole, the book is of great value in arriving at an understanding as to structural changes in the organs which manifest themselves as disease during the life of the individual.

E. H. NIDISH

FOOD AND HEALTH By R. H. A. PLIMMER, D.Sc. (London), Professor Chemistry, University of London, and VIOLET G. PLIMMER. Colored frontispiece and diagrams in the text. Longmans, Green & Co., 39 Paternoster Row, London, E. C. 4, New York, Toronto, Bombay, Calcutta and Madras, 1925

This handbook gives a splendid summary of the essential elements in a correctly balanced diet. It is particularly interesting, first because of the simple and readily understandable way the book is written, and secondly, because of the use of an illustration called the "square meal."

Vitamines are very carefully gone over and there is a splendid chart in the front of the book that shows the different foods which are rich and poor in vitamins, so at a glance one can tell what to eat and what not to eat. It is a splendid book from which to get an idea of the basic principles of diets.

KENNETH MACINNES

THE MEDICAL FOLLIES An Analysis of the Follies of Some Healing Cults, Including Osteopathy, Homeopathy, Chiropractic, and the Electronic Reactions of Abrams, with Essays on The Antivivisectionists, Health Legislation, Physical Culture, Birth Control, and Rejuvenation. By MORRIS FISHBEIN, M.D., Editor of the *Journal of the American Medical Association* Boni & Liveright, New York, 1925

The "Medical Follies" is another conspicuous and signal contribution to medical literature by the scholarly editor of the A. M. A. His canvass is big and his colors are thrown on thickly but with accurate aim and unerring skill. He pictures the truth as he sees it, and as the archives of the A. M. A. will tell anyone who seeks it, as the author has done. The Follies, like its well-known namesake on Forty-Second Street, is not devoid of humor, which is not without its sting and gives it a filip like a good cocktail.

NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL. 26, No 10

NEW YORK, N Y

MAY 15, 1926

Medical Society of the State of New York ANNUAL REPORTS 1925

REPORT OF THE SPEAKER

To the House of Delegates

GENTLEMEN

The relation of the Federal and State Governments in control of the affairs of the Nation and concerned with the welfare of the people, forming a close union, working for the common good of all, may be used as an illustration of that which exists between the American Medical Association and its constituent State organizations

The American Medical Association is doing notable work for the Medical profession and through it for the public at large, while the State Societies are doing the same thing in detail for the profession and through it for the people of the States

This service for the community, as expressed in the preservation of health and the prolongation of life, is enhanced by the close union of the National and State bodies which is essential to greater efficiency and co-operation in the maintenance of individual and public health and in the enlargement of the field of usefulness for the profession as a whole

For better understanding and co-operation it is recommended more urgently than heretofore that the delegates to the American Medical Association should take back to the profession of the State the message of the national body as observed by the delegates of the State who participate in the work of the House of Delegates of the American Medical Association

The Trustees reported that the matter of solicitation of subscriptions to the JOURNAL and other publications of the Association has been conducted in the several states in co-operation with the officers of Constituent Associations, effort being made at the same time to secure

members for the County Associations. The result reported in Georgia and New Jersey were 232 applications for membership, 413 subscriptions for the JOURNAL and 39 subscriptions to the special journals and is evidence of the desirability of this procedure.

The Section on Preventative and Industrial Medicine and Public Health in conjunction with the Section on Ophthalmology secured the adoption of the following important recommendation

"Every individual owning a motor vehicle of the self-propelling type, shall be required to present to the Motor Licensing Board in each state a certificate from a reputable physician (the standard of such medical fitness shall be licensure to practice medicine or surgery) in which the points regarding visual standard are certified. The applicant should have vision in one eye at least 20/50 and vision of at least 20/100 in the other eye with or without glasses. He shall have no disqualifying defects in either arms or legs and must be able to hear low spoken voice at five feet, the mentality of the applicant must be adequate and the heart's action reasonably healthy."

It might be well to add that the applicant should not be addicted to alcohol nor narcotic drugs

The House of Delegates requested that every member of the American Medical Association subscribe for *Hygeia* and that the magazine be kept in reception rooms in order that subscriptions may be encouraged among the laity. The Speaker has complied with that request and the circulation has been increased by some readers wishing to possess the magazine.

The House adopted, at the request of the Reference Committee on the Board of Trustees, a

PHYSIOLOGICAL CHEMISTRY A Text-book and Manual for Students By ALBERT P. MATHEWS, Ph.D., Professor of Biochemistry The University of Cincinnati, O. Fourth Edition Illustrated William Wood and Co., New York, 1925 Price, \$6.50

Physiological chemistry as outlined in this new edition lends itself to great commendation. The subject is presented in a thorough and systematic manner and any medical student or practitioner would find many a chapter to absorb his interest. The book is divided into three parts. First the author takes up the chemical constituents of the body tissues. Second, the chemical and metabolic changes that take place in the body, and third, the practical methods used in the determination of these various changes. A knowledge of these various processes that are constantly going on in the body is indispensable to the rational treatment of disease. Methods are described which have practical application in the diagnosis and treatment of such diseases as nephritis, diabetes, and other metabolic disturbances, by the use of the newer methods of chemical blood analysis. These are only a few of the interesting features found in this book.

E. H. NIDISH

AN APPROACH TO SOCIAL MEDICINE. By FRANCIS LEE DUNHAM, M.A., M.D. Octavo of 242 pages. Baltimore, Williams and Wilkins Company, 1925. Cloth, \$4.00.

This volume might well be considered an exhaustive treatise analyzing those problems that so often confront both the physician and the social service worker in their dealings with the sick. Unsound minds so frequently dwell in abnormal bodies that the modern physician, it would appear, must be somewhat of a psychologist, as well as a psychiatrist, appreciating fully the significance of "social relativity," "social criteria," etc., and able to recognize a "behavioristic tendency" at a glance.

As the author sees it, the purpose of Social Medicine "is to further the application of scientific methods of organization to man's social habits in order to determine their usual biological characteristics, to discover the sources, causes and effects of instability and to establish a sympathetic equilibrium between the organism's innate and acquired tendencies." In a section devoted to Human Energies and Social Forces the author considers the role played by personality, instinct and conduct, standards of living, food, shelter, human fellowship, etc., in the development of physical and mental health, both for the individual and the community. A discussion of general and preventive medicine and social problems naturally leads to a consideration of venereal disease and its control, cancer, tuberculosis, alcoholism, drug addiction, cripplehood and mental disorganization. In the opinion of the author "the venereal question fundamentally is one of personal hygiene in its relation to infectious phenomena, to be presented in the school curriculum to each individual during early adolescence, as a topic in the course on general infection and immunity." Concerning alcohol "agreement is general that the abuse of alcohol is responsible for a large proportion of the crimes of violence, of industrial inefficiency, of poverty and misery, of suicide, and of sexual offences." As for drug addiction "the use of narcotic drugs in the United States is diminishing slowly." The author's views on these three problems will not be universally subscribed to by those qualified to speak.

An appendix contains a number of forms which have been found of value in eliciting from patients personal, physical, psychologic and social data.

FRANK E. MALLON

MODERN OPERATIVE SURGERY Edited by H. W. CARSON, F.R.C.S., Eng., Senior Surgeon, Prince of Wales' General Hospital, Tottenham, Lecturer on Abdominal Surgery, North-East London Post-Graduate College. In Two Volumes with 735 Figures and 6 Plates. William Wood and Company, New York, 1925. Price \$20.00 set.

"This work is an attempt to present to the Profession an authoritative survey of the whole range of modern surgical operations." Thus Modern Operative Surgery is introduced by its editor who speaks for two dozen English authors working under his supervision. Such procedures as seem to have outlived their usefulness have been omitted and among the new operations only those which have proved their value have been included. This plan seems a sensible one and has been followed in a discerning way.

The surgical anatomy involved in many of the operations is adequately presented and the indications for operation discussed. After-treatment is emphasized and statistics of results of the various operations are frequently noted. The technique of operations is clearly outlined, the necessary instruments are enumerated and the appropriate anaesthetic in each case is indicated. By the way, the anaesthetic which is frequently recommended by these English surgeons is chloroform or C.E. In America this would not be accepted by the vast majority of operators or anaesthetists. However, in only a comparatively small number of instances would American surgeons be likely to object strongly to the methods advised in these volumes. The treatment of fractured patella by means of sutures of soft iron wire is probably one case in point. The statement "As a general rule, most empyemas should be drained as soon as they are diagnosed" would at least arouse discussion on this side of the water.

In the treatment of lung abscess no mention is made of the cautery operation of Graham, but this is probably due to the editor's declared intention to describe only what has definitely proven itself of value. Blood transfusion is quite fully discussed but the omission of a description of the method of Unger or of Miller, which have been accepted in so many of our hospitals, mars the completeness of this chapter.

The description of amputation of the breast includes directions for the holding of the arm by an assistant. We wonder if the author has ever experienced the comfort contributed by a long, narrow, metal shelf for the arm which shelf can be thrust under the patient's shoulder and will hold the arm at any desired angle.

The Rammstedt operation is given as the accepted treatment for congenital pyloric stenosis, but the use of a general anaesthetic for tiny, ill-nourished infants seems unnecessarily dangerous to those who employ local anaesthesia with utmost satisfaction in these cases.

For diagnosis of subphrenic abscess the use of an exploratory needle passed through the diaphragm is advised, for its treatment the transpleural operation is favored.

In the treatment of hyperthyroidism ligation of arteries has seldom been found necessary if proper medical care has been prescribed for a sufficient length of time before thyroidectomy. Chloroform anaesthesia is condemned in this condition and a preference for open ether administration is expressed. Local anaesthesia is sometimes resorted to. Gas-and-oxygen is not mentioned in this connection.

Among gynaecological operations one partial perineorrhaphy and one complete perineorrhaphy are described in marked contrast to the common run of books in which many different procedures for the same purpose are depicted. Subtotal or supravaginal hysterectomy is recommended for the majority of cases of fibroids, fibrosis and metritis.

The subject of prostatectomy is very fully considered. Under the head of haemorrhage no mention is made of the efficient Pilcher bag or of any similar apparatus.

These volumes have been carefully edited and their multiple authorship would hardly be suspected. They are presented in an attractive form and are illustrated in a way to help the meaning of the text. Only the highest commendation would characterize an honest review of this work which will undoubtedly be welcomed by all surgeons.

T. B. SPENCE.

established a section on Radiology. The following resolution was adopted at the request of the Reference Committee on the Judicial Council:

Resolved, That it is the sense of this House of Delegates that the periodic health examinations should be conducted by medical men and neither dominated by nor controlled by lay organizations, for the reason that the relation between the patient and the physician is an individual matter and anything that disturbs such relationship is detrimental to the best interests of the patient.

Resolved, That it is the sense of this House of Delegates that every Fellow and Member of the American Medical Association should live up to the spirit and letter of this resolution.

The address of the President, J. Basil Hall of the British Medical Association and its official delegate to the annual session of the American Medical Association contains a valuable practical lesson on Medical Organization. In 1912 the Medical Profession in England was compelled to face the National Health Insurance Act and the Association was poorly organized to meet this great question. The members disliked contract service with the government, there was a great outcry and they were not going to submit to the provisions of the Act. Mr. Lloyd George said if the Medical Profession as a whole did not come in to work with this Act and along the suggested lines, he had up his sleeve, sufficient medical men to establish a State Service and work it on lines which the members of the Association wished to avoid. Finally there was a great panic, the organization tumbled to pieces and every one went into the Act. It was a pitiable spectacle because they went into it after they said they wouldn't. The British Medical Association came in for a good deal of abuse. That was thirteen years ago, but as now organized the British Medical Association is in the opinion of many people the strongest trade union in the British Isles.

Prior to the war each panel doctor received seven shillings or seven and sixpence that is, nearly two dollars for every patient on his panel list. During the war the payment was raised to twelve shillings and sixpence for each name on the panel list, it was a contract. Two years ago the Government said that the payment must be reduced as the cost of living had fallen and that twelve and sixpence was too much. The Minister of Health said that he was going to pay seven shillings and sixpence. The Committee of the British Medical Association said that the payment should be nine shillings and sixpence. The friendly societies said that six shillings was quite

enough for any doctor. The British Medical Association was willing to have arbitration, the Minister of Health said he had no use for arbitration, he had made up his mind that it was going to be seven and sixpence and the Association would have to take that. The British Medical Association replied that he might find himself without any panel doctors to work the Act. His retort was that the Medical men tumbled into the Act quickly enough when it was first introduced and he thought they would fall into line again.

The British Medical Association then sent out forms of resignation to all the panel doctors throughout the Kingdom and within ten days the Minister of Health received 96 per cent resignations. He was left with 4 per cent of the doctors to carry on the Act. He then said he thought arbitration was not a bad thing after all. A commission was formed and after many days the arbitration awarded nine shillings per patient and that award to remain in force for five years. A wonderful exhibit what organization can do.

When the New York delegation made known its intention to nominate for President Elect its favorite son Dr. Wendell C. Phillips, there was in the field a candidate from a middle western state which had not been honored with the presidency in forty years. We all recognized his ability and knew that he was deserving of the presidency, but not this year. The popularity of our candidate grew so rapidly that the name of the opposing candidate was not presented to the House and Dr. Phillips had the unusual honor of being elected unanimously by voice vote, President-Elect of the American Medical Association.

It is my sad duty to call your attention to the death of one of your delegates to the American Medical Association, Dr. Grover W. Wende, a former President of this Society. He will always be remembered by those who were privileged to know him as one worthy of honor and esteem. He was an eminent dermatologist and a man of wide scientific attainments. His delightful personality and sterling character won for him a host of devoted friends.

The kind consideration and helpful cooperation the speaker has always received from the members of the House of Delegates have lightened the work and made most pleasant the duty of presiding at sessions of this House.

Respectfully submitted,

E. ELIOT HARRIS, *Speaker*

March 15, 1926

The Reference Committee on the Speaker's Address recommended the adoption of the Speaker's suggestions regarding the manner of electing the Trustees and the Delegates to the American Medical Association. The election was held in accordance with those suggestions. See page 469.

recommendation that a Council of Physical Therapy be created so as to include all physical agents used therapeutically and that physicists be added to the personnel of the Council. The Board of Trustees has recently created such Council of Physical Therapy consisting of eleven members.

The work of the Council of Pharmacy and Chemistry always received the highest commendation from the House of Delegates but the last House emphasized its appreciation of the members of the Council who serve faithfully, unselfishly and without remuneration. The same Reference Committee recommended that in referring to quack remedies the term *nostrum* should be used instead of patent medicine. After explaining in detail why the use of the words patent medicines should be discontinued in the JOURNAL as synonymous of *nostrums* the recommendation was adopted without dissenting voice.

The Reference Committee's report on Council of Medical Education and Hospitals contains the following:

The problem of nurse education, which has become an acute one, shows small progress, in the Council's report, toward solution. The present course of nurse education is not providing nurses willing to do the ordinarily accepted duties and accept the ordinarily expected responsibilities of nursing the sick. As in the education of the medical student, science is overshadowing art in a profession which is largely, if not mainly, dependent on art for its successful practice. The plan of a joint committee of nine members from the nursing profession and three members from the medical profession may develop a solution, but, if so, much time will be occupied. It seems possible to your committee that the establishment of numerous small hospitals with their associated training schools for nurses may in a measure, at least in the smaller communities, offer a solution. In view of the importance of the problem in respect to the practical application of our professional duties, the committee believes that the survey recommended by the Council should have the support of the Association and would recommend that the Board of Trustees give such financial assistance as its judgment indicates. (29) (31)

President Pussey recommended that delegates to the House of Delegates of the American Medical Association should be elected in the preceding calendar year and not a few days before the meeting of the House. This would give new delegates an opportunity to familiarize themselves with the business coming before the House and such study would intensify their interest and responsibility in the discharge of their duties as delegates.

This recommendation of the President became more important when the House of Delegates adopted the following:

Resolved That members of Reference Committees of this House be appointed at least thirty days in advance of the Annual Session at which they are to serve.

The wisdom of the recommendation of President Pussey that Delegates to the American Medical Association should be elected in the pre-

ceding calendar year is exhibited at this Annual Meeting of our State Society where ten delegates will be elected just twenty days before the Annual Meeting at Dallas, Texas, and ten days after the appointment of reference committees as ordered by the House of Delegates.

The By-Laws of the American Medical Association provide that every third year there shall be a reapportionment of the delegates in proportion to the Membership of the Constituent Associations as recorded in the office of Secretary on April 1 of the year in which the apportionment is made. The New York State membership on April 1, 1925 was 10,396 and on the basis of one delegate to each 750 members or fraction thereof New York will be entitled to 14 delegates to serve in the next House of Delegates of the American Medical Association.

Section 18 of the New York State By-Laws provides that the delegates of the American Medical Association shall be elected in accordance with the Constitution and By-Laws of the American Medical Association. Section 2 of the By-Laws of the American Medical Association states:

"Delegates and Alternates from constituent associations shall be elected for two years. Constituent associations entitled to more than one representative shall elect them so that one-half as near as may be, shall be elected each year."

In order to conform to the By-Laws of both the American Medical Association and the State Society, I make the following recommendation.

Nominations shall be made for not less than double the number of delegates to be elected. There are ten delegates to be elected and at least twenty names should be placed in nomination.

The Ballots voted shall not contain more than ten names for delegates. In the order of the highest number of votes cast the first seven shall be declared elected as delegates for two years, the next three shall be declared as elected as delegates for one year, and the next seven as alternates for two years, and the next two as alternates for one year.

Provided the Governor signs the Act which will enable the House of Delegates to elect trustees, then the following resolution describing the manner of electing the five trustees is recommended for adoption by the House of Delegates.

Resolved, that nominations shall be made for at least five trustees. The trustee receiving the highest number of votes shall be elected for five years, the next highest for four years, the next highest for three years, the next highest for two years and the next highest for one year. In the event of a tie vote a new ballot shall be taken for the election of one of the nominees for the specific place for which such nominees are so tied.

The House of Delegates of the American Medical Association amended the By-Laws which abolished the section on Stomatology and

individuals, by the Metropolitan Life Insurance Company and by the State and local Departments of Health, and recognizing the importance of the State Society rising to an appreciation of its responsibilities in all public health matters passed the following resolution —

*Resolution Passed by the Executive Committee
January 14, 1926*

Resolved, That the President shall appoint a committee of ten, which shall include a member from the State Department, of Health, and from the State Charities Aid Association, the Director of the Academy of Medicine, the President of the State Homeopathic Society, the Chairman of the Committee on Public Health and Medical Education, the Chairman of the Committee on Economics, the President, and three other members of the Medical Society of the State of New York for the purpose of formulating a plan of campaign to make toxin-antitoxin available to every child in the State of New York and place the responsibility for its distribution upon the Medical Profession of the State in such a manner that every Practitioner of Medicine who wishes may have a part in its administration

COMMITTEE

Dr Matthias Nicoll Dr W Warren Britt
Dr Linsly R Williams Dr Frederick E Sondern
Mr Homer Folks Dr H G Weiskotten
Dr George F Raynor Dr William H Ross
Dr Charles A Gordon Dr Nathan B Van Etten

Details of the campaign are being developed in the Committee for Public Health and Medical Education in co-operation with the State Department of Health, and interested lay organizations. This campaign will be watched with the closest interest by the whole country and I trust that the Medical Society of the State of New York will live up to its possibilities

NURSING

The special Committee on Nursing has been constantly seeking a solution of a problem which is chiefly concerned with the bed side care of sick individuals. The Committee has tried to uncover basic reasons for unsatisfactory conditions by asking statements of fact from hospital heads, superintendents of nurses, registered nurses, student nurses, physicians, departments of Education and Public Welfare. All seem to admit that there is a problem. Many suggestions of remedy have been made, differing widely, but no real solution has been presented or agreed upon. The Executive Officer has worked night and day upon this problem and has collected an astonishing mass of material which will require a considerable time to digest

The attraction of public health, executive and industrial nursing service apparently is respon-

sible for the shortage of nurses for bed side work and seems to some observers to indicate necessity for a simpler curriculum to provide for a basic trained nurse who would be well equipped with a knowledge of the art of nursing—and that those who desired further knowledge of the sciences to equip themselves for special or executive positions, should be given post graduate opportunity

I recommend for your consideration the suggestion that all trained nurses should receive basic training in training schools for nurses connected with hospitals or sanitariums giving a course of at least two years and registered by the Regents of the University of the State of New York. The curriculum should be revised so as to provide clinical instruction, class room lectures and demonstrations to properly fit the student for their work as nurses in hospitals and in the home

Graduates after passing the State Examinations shall be registered by the Regents as Registered Nurses—Such registered nurses may become public health or other specially designated nurses after being properly admitted to Post Graduate Schools for nurses approved by the Board of Regents and passing the required examinations

LEGISLATION

Pursuant to the direction of the last House of Delegates I appointed a Committee to prepare amendments to the Medical Practice Act and this Committee under the able chairmanship of Dr John E Jennings of Kings, worked hard all summer to produce a bill which would satisfy every element of our Society. Perfection of course is unattainable and unanimity of opinion is impossible in such a highly individualistic group of workers as comprise the Medical Profession. While the great majority are reasonably satisfied with the work of this Committee an irreconcilable militant minority emphatically object, and we are again in the same position we held last year. If the bill fails of passage, I recommend that another committee be appointed and that we try again. The Workmens' Compensation bill prepared by a Special Committee is in committees of Senate and Assembly and is likely to lie over with most of the compensation matters until another year

Dr Shaw the Chairman of the Committee on Legislation and the Executive officer have conducted the work of the Committee and the Legislative Bureau in a very satisfactory manner have made many friends for the Society and have held legislative hearings at which impressive numbers of representatives of lay organizations have appeared in support of our measures

The Executive officer has justified his office and his tenure of it, by responding most actively to constant calls from every part of our organization. He has been a real liaison officer between members and County societies, district branches,

REPORT OF THE PRESIDENT

To the House of Delegates

GENTLEMEN

The Medical Society of the State of New York is concluding a year of unexampled activity which must be credited to an unusual stimulation of interest in new and developing ideas and which has been carried forward with a remarkable degree of team work between officers and committees

The Executive Committee of the Council at regular and special meetings has carefully studied the complexities arising from increased income, and from financial conditions which have gradually developed into problems. A budget and business sub-committee, apportioned income to expense at the beginning of the year and the Society has lived within its resources.

With growing activities dwarfing out-worn methods, and with the immediate prospect of removing our operating plants to the new Academy of Medicine, it would seem opportune therefore to recommend that a firm of efficiency and accounting experts be employed to study our needs and equip us with a complete modern business system.

The Journal has shown vigorous growth under the guidance of my successor in the Editorial Chair, Dr. Wightman and with a continuation of his able and enthusiastic efforts may well become one of the best medical Journals in the country. The increased income from advertising during this year gives reason to believe that our publications may not only become self supporting but may produce a balance of revenue that may be applied to other organization needs.

The society has been ably guided, counseled and defended for many years by Mr. George W. Whiteside whose name has become a talisman of comfort to all of our members. His remarkable talents have won recognition outside of our field and he has been obliged to accept a call to more lucrative opportunities. His charming personality has won a warm place in the esteem of all with whom he has come in contact and we congratulate him upon his preferment and wish him abundant success.

His former partner Mr. Lloyd Paul Stryker has succeeded him as our counsel and has already shown abilities as a speaker and adviser that amply justify this new relationship.

The question of legal defense and insurance is acute. All of our members should be defended to the limit of our ability. The matter of indemnity is a personal matter which touches the financial existence of each one of us. He is venturesome indeed who dares to practice medicine without it. Fifty-three per cent of our members carry insurance with the Aetna Insurance Company. A few retired members who do not practice do not need insurance. We do not know how many are

insured in other Companies but a safe estimate indicates that twenty per cent of our members carry no protection—are taking a gambler's chance with everything they possess and if many suits are brought against them may seriously involve the Society's finances.

A special committee has been carefully studying these questions for several months and will be prepared to report to the next Council.

Very few of you know the amount of work done by the Committee Chairmen. You observe the finished product and dismiss it with approval or disapproval, you do not know that the Chairman of the Committee on Scientific Work has been developing his program during the entire year and has already to offer you one of the best scientific programs that you have ever seen as the result of daily thought and correspondence. The speakers have been so carefully selected that they must feel themselves honored in being invited and those who co-operate in the Syphilis Demonstration must feel a great satisfaction in participating in an unprecedented exhibition.

The Chairman of the Committee on Economics has given earnest study to our social and economic problems. He has traveled all over the State, has had many conferences with State Departments, has visited County societies, has assisted and stimulated the work of committees, assisted the Chairman of the Special Committee on Workmen's Compensation Laws. Dr. Hourigan, in preparing the bills now before the Legislature, has assisted the Special Committee on Nursing, has warmly advocated periodic health examinations, and has labored assiduously to waken the interest of the general practitioner in his own problems.

The Committee on Public Health and Medical Education as was expected has carried on a very extraordinary piece of work. The Chairman has given hours of every day in the year to the development of the plan for carrying post graduate Education to the doctor at places convenient to his home. Besides its Educational value, this work has stimulated State-wide interest in the State Society and a realization of the value of membership in the organization. The co-operation of the Health Department and the interest of lay organizations have been enlisted in a surprising degree and an unlimited field is opening with a most promising prospect.

I recommend that this work be heartily endorsed by this House and that the Committee be assured of every possible assistance.

PREVENTIVE MEDICINE

The Executive Committee of the Council appreciating the importance of a definite proposal for carrying out a preventive medicine campaign endorsed by the State Charities Aid, by interested

REPORT OF THE SECRETARY

To the House of Delegates

GENTLEMEN

Among the many duties imposed upon the Secretary is that of submitting an annual report to the House of Delegates. Such report must be necessarily more or less statistical and deal mainly with the business phase of the Society's affairs.

When the Secretary, after long and insistent persuasion, consented to assume office, he did so in full knowledge of the fact that his selection was due solely to his training and experience in secretarial work. It is for this reason that he departs from the time honored form of report and presents a brief survey of existing conditions and needs. He makes no recommendations, preferring to make suggestions of changes which, in his opinion, might be of benefit to the Society and which might serve for the guidance of a possible committee on reorganization. He would ask, however, favorable consideration of the recommendations regarding these matters which are incorporated in the report of the President.

There is nothing in this report that is intended for, or that should be construed as, criticism of any individual or individuals, it is the "system" and the "system" only, that is under discussion. Furthermore, it should be distinctly understood that it concerns the business side and not the policies of the Society. It is the conduct of the affairs of his own office and the relation it bears to the component County Societies, the officers and the various committees that are commented upon.

To criticize or even comment without the suggestion of remedy is unfair and unwise and if not actually destructive is, to say the least, productive of more pronounced uncertainty and disorder.

The Secretary therefore begs to submit the following:

THE SOCIETY IN GENERAL

The basic organization of the Society is as near perfection as possible and its Constitution and By-Laws are second to none.

During the past few years, it has shown a steady growth in membership, has more than doubled its income, has taken on many new activities of interest and value to the profession and to the public, and has won its way to a position of importance and influence in the State. Never have its committees functioned with such enthusiasm and earnest endeavor and never have the results been more gratifying.

If these statements are true, and no one can deny that they are, wherein lies the reason for critical comment? What is lacking?

The reason lies in the indisputable fact that the

Society, on account of its increased income and the adoption of activities which stretch far beyond the confines of strictly medical work and involve expenditures of considerable amount, has become, in a measure, a business as well as a membership corporation. As a business corporation, it can not maintain a healthy growth without adopting a policy of business efficiency and modern methods of office conduct and control. These are the lacking elements.

The Society has grown but the methods of conducting its affairs have not kept pace with the growth, they being today substantially the same as those of years ago. With the exception of the establishment of an Executive Committee and the raising of the dues, no attempt has been made to reorganize these methods in accordance with modern progress or with the increased needs of the Society. There consequently exists a constant and confusing overlapping of duties and authority and no real co-ordination.

This has been the fault of no one in particular but has been brought about by force of habit, by a reluctance to shake off the trammels of precedent and tradition and by a dread of incurring extra expense.

These statements are plain matters of fact born out both by the records and the lack of records and are very mildly put. In fact, were it not for the loyalty, the conscientious care and tireless work of the Business Manager, Miss Baldwin, the machinery would have ceased to function and fallen to pieces long ago.

THE SOCIETY'S OFFICE

The Secretary of the Society, who in accordance with the By-Laws, is also Secretary of the Council, the Executive Committee, and the Censors and a member of all standing committees is essentially the business officer and should be recognized as the head of the office *de facto* as well as *de jure*.

He should familiarize himself with the conduct of the office and keep in intimate touch with the affairs of the Society as upon him devolves the responsibility of any failure or neglect. The details should be left to the Business Manager and her assistants but under his constant supervision.

There are at present three main activities carried on in the office, which for convenience may be designated as Secretarial, Financial and Editorial. It would contribute greatly to the future welfare of the Society if these activities were made separate departments each under its own staff but correlating through the Business Manager.

The present quarters are inadequate and much of the office equipment obsolete. This cannot be remedied until the quarters in the new Academy

committees and officers in the general promotion of intelligent understanding of our problems and in the collection of masses of information and opinion from many sources for the use of committees on nursing, legislation, scientific progress, public health and education, and economics. He has been successful in winning for us many friends among legislators and lay organizations. His fine educational equipment, and his growing experience in a developing office are qualifying him for great future effectiveness.

PUBLIC HEALTH

This year has been marked by an unusual appreciation of the importance of public health and of the basic understanding that it can be carried to its highest possibilities only by the earnest co-operation of all physicians. Every physician should constitute himself a guardian of the health of his community as affecting the people who place themselves under his care. He should merge his individualism into county organizations, and assert his intelligent leadership in all public health activities.

The Governor of the State has publicly and privately consistently stressed the value of the humanities and the relationship of the medical profession to them. Lay organizations have come to realize that they can not attain their ideals without such co-operation. The State Committee on Tuberculosis of the State Charities Aid Association has by formal resolution elected the succeeding Presidents of the State Society to membership upon their Executive Committee.

The Commissioner of Health has shown a consistent advocacy of the value of organized medicine as exemplified by the State Society. He invited the President to address the Conference of Health Officers and Public Health nurses in Saratoga in June and has continually given us the warmest support.

The Department of Labor through the Industrial Commissioner has invited the sympathetic interest of the Society in their problems.

The President and Secretary developed the medical program of the Safety Congress at Syracuse and presided at two sessions, at the same time collaborating with the State Society of

Industrial Physicians and establishing mutually helpful cordial relations.

TRI-STATE CONFERENCE

A conference of the Presidents and Secretaries of the Medical Societies of the State of New Jersey, Pennsylvania and New York and the Editors of the State Medical Journals was called on February twenty-sixth with the idea of discussing questions of mutual interest and importance to contiguous States. The questions discussed were Post Graduate Education carried to the Doctor in the field, Periodic Health Examination, Malpractice Defense and Indemnity, and Campaigns for the promotion of Preventive Medicine, and revealed a mutually helpful spirit among the officials of organized medicine in these three States. I recommend that these Tri State Conferences be continued and encouraged by the approval of the House of Delegates.

DR. A. WALTER SUITER AND DR. GROVER WENDE

During the year two former Presidents have been taken from us by the grim hand of death. Dr. A. Walter Suiter, an enthusiastic officer who served the Society with merit and devotion and who gave concrete evidence of his love for the Society by bequeathing to the Society a part of his residuary estate, and Dr. Grover Wendt whose brilliant career met untimely conclusion by an immediately fatal accident on February ninth. Dr. Wendt was well known and beloved by the members of this house and his passing out of our lives leaves us with a sense of personal loss.

I recommend that when this House of Delegates adjourn it does so in honor of Dr. A. Walter Suiter and Dr. Grover W. Wendt.

I am deeply appreciative of the honor and privilege of serving organized medicine as your President and I am grateful for the unfailing support given me by every officer and committeeman in the Society.

The future is a brilliant one and I am confident that the Medical Society of the State of New York will realize its possibilities.

N. B. VAN ETEN, President

March 15, 1926

The Reference Committee approved the recommendation that a modern business system be instituted in the office of the State Society. See pages 463 and 464.

The proposal to present Mr. Whiteside, former Counsel, with a set of engrossed resolutions was approved. Page 464.

Participation in the Tri-State Conference was approved. See page 463.

The manner of conducting the JOURNAL was approved. See page 464.

The suggestions regarding the recognition of nurses after a basic training of two years, were approved. See page 459.

of the office to advise with the Secretary on matters requiring immediate attention

The list of honor counties whose membership shows all dues paid for the year is as follows: Columbia, Fulton, Greene, Orleans, Rensselaer, Richmond, Rockland, Schenectady, Schuyler and Yates

The Secretary takes pleasure in publicly expressing his thanks to the Business Manager for her valuable assistance and for her earnest and effective work, to the Executive Officer for his hearty support and willing co-operation, and to the District Branches for the cordial greeting and hospitality extended to him at the District Meetings. To the President, he extends his sincere thanks for and appreciation of his helpful advice, his many acts and words of kindness and his never-failing courtesy. They entered upon their duties as acquaintances, they part as friends.

The Report of the Secretary was accepted without recommendations. See page 463

See also the approval of the recommendations of the President regarding the reorganization of the central office, page 464

For his fellow members of the Executive Committee, the Secretary entertains deep feelings of friendship and admiration. Their loyalty to the ideals of the profession and devotion to duty, their sacrifice of time and practice for the welfare of the Society should evoke feelings of thankfulness and gratitude.

The Secretary records with sorrow the deaths of Grover W. Wende and A. Walter Suiter, Ex-Presidents of the Society, and Wm. H. Purdy, a former Vice-President and for many years a member of the House of Delegates. In memory of Dr. Wende and D. Suiter appropriate action has been taken by the Council. If further tribute should be taken by the House, the name of Dr. Purdy should be included.

Respectfully submitted,

D. S. DOUGHERTY,

Secretary

March 15, 1926

REPORT OF THE COUNCIL

To the House of Delegates

GENTLEMEN:

The Council has the honor of presenting the following report:

Four meetings have been held, in Syracuse on May 14 and in New York City on June 3, October 29, and December 10.

The minutes of these meetings have been published in the JOURNAL and it would be needless repetition to incorporate them in this report.

In accordance with the provision of the By-Laws governing the constitution of an Executive Committee, W. H. Ross, F. H. Flaherty, E. Eliot Harris, G. M. Fisher and J. A. Card were elected to serve with the President and Secretary on such Committee.

The Executive Committee has held nine meetings and has twice submitted a referendum to the Council on matters pertaining to the Medical Practice Act.

The Special Committee appointed in accordance with the resolution of the House of Delegates to draw up a Medical Practice Act reported to the Executive Committee and, on referendum vote, this report was adopted by the Council. On the second referendum vote, the Bill as amended by the Board of Regents was approved.

The Legal Counsel, having made new professional affiliations, was compelled to resign his

office and the resignation was accepted with sincere regret and appropriate resolutions.

In order that there might be no confusion or delay in the work of the Legal Department, the Executive Committee appointed as Counsel, Mr. Lloyd P. Stryker, who as Mr. Whiteside's partner has handled much of the Society's work. This appointment was made contingent upon the future action of the Council.

The Committee also appointed Drs. Ross and Card a sub-committee to make an intensive study of the work of the Department.

The resignation of Dr. James N. Vander Veer having been accepted with regret, the Executive Committee, on nomination of the President, appointed Dr. Henry L. K. Shaw, Chairman of the Committee on Legislation.

The following appointments were made: E. R. Cunniffe, Chairman of Committee on Arrangements; O. S. Wightman, Editor-in-Chief; Frank Overton, Executive Editor; Joseph S. Lawrence, Executive Officer; J. C. Jennings, Chairman of Special Committee with power to draft a Medical Practice Act; E. Eliot Harris, W. H. Ross and D. S. Dougherty, as Publication Committee.

Two conferences with the officers of the Medical Society of the State of New Jersey and of the State of Pennsylvania have been held at which matters of mutual interest were discussed.

of Medicine building are ready for occupancy in the fall. A complete modern filing system should be installed and kept up-to-date by a competent clerk. All old records should be carefully collated and filed and a history of the Society thus preserved.

The Secretary is informed that many important documents are in the hands of ex-presidents, former committee chairmen and others, these should be forwarded to the Secretary for filing with the permanent records.

REPORTS AND COMMUNICATIONS

In order to expedite business and promote efficiency, all reports of officers and committees should be sent to the office and be in the hands of the Secretary not later than twenty-four hours before the meeting of the body to which they are to be presented. In especially important matters requiring careful study, sufficient time for the making and distribution of individual copies should be allowed. This rule should be rigidly observed not only by committees but by all officers, the President not excepted. The President should insist that reports be sent in this manner and not sent to him personally. The dignity of his office should be preserved.

For the purpose of preserving orderly methods and correct records, all official communications should go through the Society's office and from there be distributed to the proper officer or committee. If this method of correspondence were adopted by the County President and Secretaries, much of the present overlapping and confusion would be avoided. There must be a properly organized channel for communications and this can be maintained only through the State Secretary. This does not apply to communications on legislative matters which should be sent to the Legislative Bureau at 51 Chapel Street, Albany.

Resolutions offered in the House of Delegates or to the Council should be in writing and in duplicate, one copy for the reference committee and one for the official files.

Where at all possible, resolutions presented to the House should be acted upon at once. The habit of referring everything to the Council and thence to the Executive Committee serves to clog the wheels of progress with inconsequential matters and causes many important ones to be neglected.

THE EXECUTIVE OFFICER

This officer should be in closer official touch with the Secretary and upon him should devolve certain duties which now, according to the By-Laws, are delegated to the Secretary, a proper collaboration would be of benefit to both and to the Society.

His duties which, with the exception of his legislative work, appear, even to him, indefinite

and nondescript, should be clearly defined and his office put upon a more solid and dignified basis.

LEGAL DEPARTMENT

The only point of contact with this department is that which concerns the proper recording of all transactions of the Legal Counsel with the Society. All data relating to malpractice defense and all written legal opinions rendered by the Counsel should be kept on file.

All requests for malpractice defense should be made through the Secretary who, after investigating the standing of the applicant and making the proper record, should forward such request to the Counsel. A record of the subsequent conduct and disposal of the case should be filed with the Secretary.

BOARD OF TRUSTEES

The Secretary is firmly convinced that the Amendment providing for the election of a Board of Trustees should be adopted.

The Society now enjoys an income of over one hundred thousand dollars and there is urgent need of a Board of this character to take charge of and invest the funds and carefully supervise their expenditure. A Council or an Executive Committee, the complexion of which changes annually, should not have this financial responsibility thrust upon them and should not be expected to assume the duties of custodians of funds. With this annual change and the consequent shifting of responsibility, careless waste and extravagance may creep in without being the fault of any one except those who neglected to adopt the safeguards of business efficiency and modern financial methods.

This amendment concerns the finances of the Society and in no way affects its policies or economic activities.

As the members of the Executive Committee are apt to reside in widely separated sections of the state and as the Committee meets but once a month, there should be appointed from its members a small subcommittee residing in the vicinity

REPORT OF THE COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION AND THE COMMITTEE ON POST-GRADUATE MEDICAL INSTRUCTION

To the House of Delegates

GENTLEMEN

The Committee on Public Health and Medical Education and the Committee on Post-Graduate Medical Instruction have functioned as one committee.

The steadily increasing group consciousness of organized medicine, and its growing desire to assume leadership in the solution of the great problems of public health, fix upon us a very definite responsibility

In the continuous education of the practising physician we see the greatest single contribution that organized medicine can make. Most of our activity has been in that field.

In no other State where graduate education is being done do conditions parallel New York. Our problem is unique. We have attempted to solve it in our way, slowly and conservatively, yet making use of available resources.

The geographical makeup of our committee was a distinct advantage in our preliminary survey of the State, but District Branch organization was soon found to be unwieldy, in only one district has it been possible to work out the problem that way.

This survey was followed by a questionnaire to all the counties, and our early work was based upon its information.

THE QUESTIONNAIRE

- 1 What is your County Society doing in the line of graduate teaching?
- 2 Has your Society a committee on "Graduate Medical Education?" If so, who is chairman?
- 3 Has your Society any plans, tentative or otherwise, with regard to graduate teaching?
- 4 What facilities exist in your county to conduct extension courses such as meeting places for lectures, lantern, motion picture machine, hospitals, etc?
- 5 Are there geographical divisions in your county which make it difficult to assemble at a central place or which would make it necessary in any plan to provide for your Society and geographical groups? If so, what are they?
- 6 What in your opinion would be attractive to your members in graduate teaching?
- 7 Has your Society a Public Health Committee? Who is chairman?
- 8 How many physicians in your county? How many are members of the County Society? Are most of them in general practice? Under average conditions what would be the best months of the year for extension work? How often and at what

time of day would lectures or clinics be best held?

- 9 Are there any medical societies of importance, special or otherwise, in your county aside from the County Society?
- 10 Have you any suggestions or queries with respect to graduate teaching or public health activities which you wish to submit to the committee?
- 11 Are there in your membership physicians who are able and would be willing to take teaching assignments? If so, please list them.
- 12 Should physicians of the county who are not members of the Medical Society of the State of New York be included?

Correspondence has been with the officers of county societies, and our plan of organization has slowly evolved as difficulties presented themselves.

The office of the Committee is in the Library Building of the Medical Society of the County of Kings, which generously gives us space and makes no charge for the valuable assistance given our Committee by Dr A N Thomson, Secretary of its Committee on Public Health. A high class secretarial help is provided at the cost only of hourly stenographic service, and a heavy correspondence has been handled. A pin map is used to indicate the progress of our work, and a very complete file of county educational activity has been developed.

The task has demanded an unusual amount of time and effort. Arrangements of courses or single talks involves consideration of time, weather, season, costs, needs, wants, previous courses, assignment of lecturers, postponements, cancellations, and follow-up of courses given.

For the use of our Committee the Council appropriated \$5,000, of which about \$2,500 has been expended for secretarial service and supplies, files, telephone calls and telegrams, films, traveling expenses of teachers, in a few cases small honoraria, and the distribution of the A M A Manual.

The State Department of Health early offered their full co-operation, and placed the services of their regional consultants at our disposal. Courses in obstetrics and pediatrics of six lectures each were offered to county societies as "Given by our Committee with the co-operation of the State Department of Health, practical, and as far as possible clinical."

Our spring program in obstetrics and pediatrics has been arranged largely through the efforts of Dr Dean, whose services were placed at the disposal of the Committee by the State Department of Health for a period of five weeks. During this time he visited the field and reported to

The Council and its Executive Committee have acted upon the resolutions and recommendations referred to them with as much care and consideration as within human possibility to give them but, in many cases, absence of proper data and the arguments pro and con that could have

been presented on the floor of the House, has made correct analysis and study extremely difficult

Respectfully submitted for The Council,

D S DOUGHERTY,
Secretary

REPORT OF THE COMMITTEE ON PUBLICATION

To the Executive Committee of the Council

GENTLEMEN

JOURNAL

In accordance with a resolution of the Executive Committee, passed on May 14, 1925, "that the President appoint a Committee on Publication," the President appointed Dr E Eliot Harris, Chairman, Dr Daniel S Dougherty and Dr William H Ross

At the same meeting Dr Orrin Sage Wightman was unanimously elected Editor-in-Chief of the New York State Journal of Medicine

The Council at a meeting held on June 3, 1925, re-appointed Dr Frank Overton Executive Editor

The Committee on Publication and the Editorial Board have held frequent meetings at which they have formed the policies to be carried out in the publication of the Journal

After careful consideration it was decided to publish the Journal twice a month throughout the year, and to add a department of Medical Progress under the editorship of Dr Thomas L Stedman, which would bring to the members the latest advances in scientific medicine

A full time Advertising Manager was engaged with the result that more than \$7,000 worth of new advertising has been added to the Journal since October 1st, and this promises to be greatly increased before the end of 1926

Every effort has been made to broaden the editorial policy, to create new and constructive departments and to elevate the standard of the scientific articles

The Editorial Board feel that they have only just begun their work and have many plans for the betterment and development of the Journal during the years to come

The cost of the Journal to the Society is only about \$3,500 more than in previous years in spite of the fact that there have been four more issues

published than in 1924 and a larger edition owing to the increase in membership

1925 RECEIPTS AND EXPENSES, EXCLUSIVE OF STENOGRAPHERS' SALARIES AND INCIDENTALS

RECEIPTS	
Advertisements and sales	\$18,802.17
EXPENSES	
Salary of Editors	5,150.00
Printing and Postage	27,675.93
Commissions	4,287.42

The resolution of the House of Delegates that only Medical Preparations, which have been approved by the Council on Pharmacy and Chemistry of the American Medical Association, continues to be the guide in the selection of advertisements of medical preparations used either internally or externally

DIRECTORY

The value of the Directory has been greatly enhanced by including the list of the hospitals of the state, which had been temporarily discontinued owing to war time conditions

This with the addition of the alphabetical list, which was restored in 1924, brings the Directory almost up to the high mark which had been attained in earlier editions

There is an increase of revenue of over \$2,000 in receipts from advertisements, and in spite of an increase in the cost of publication, owing to the addition of seventy-three pages and a five-hundred increase in the number of copies published, the Directory shows a decrease in the cost to the Society of over \$800

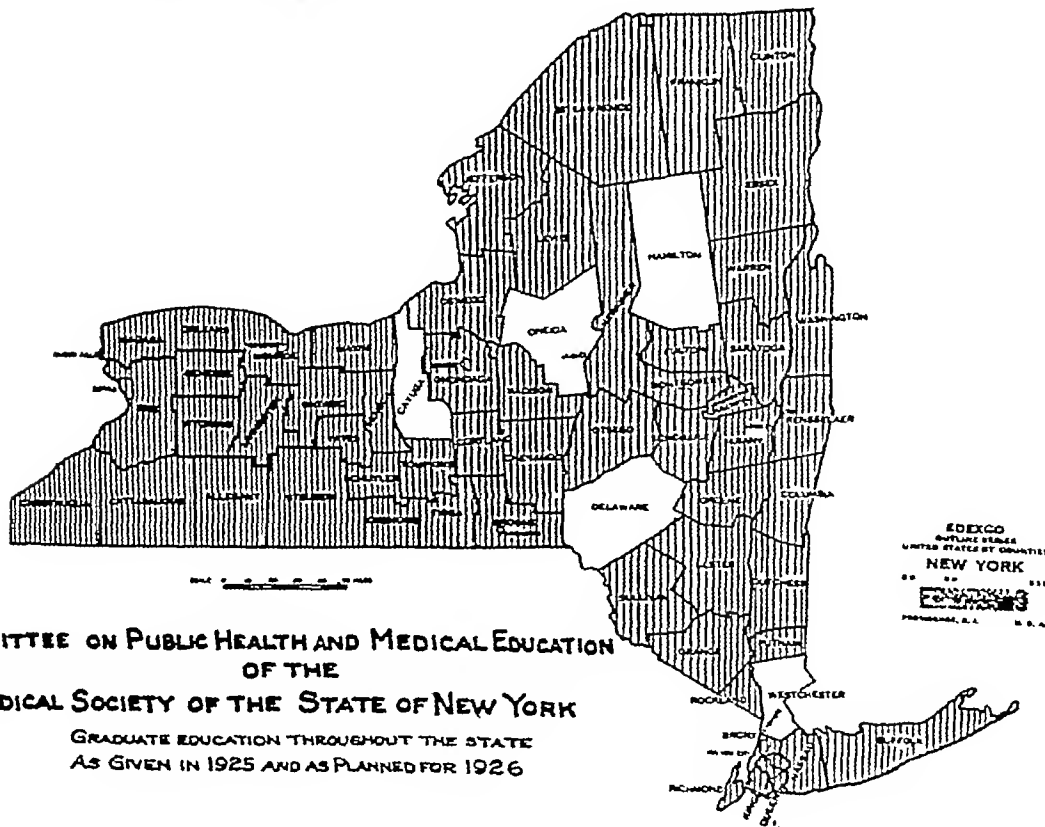

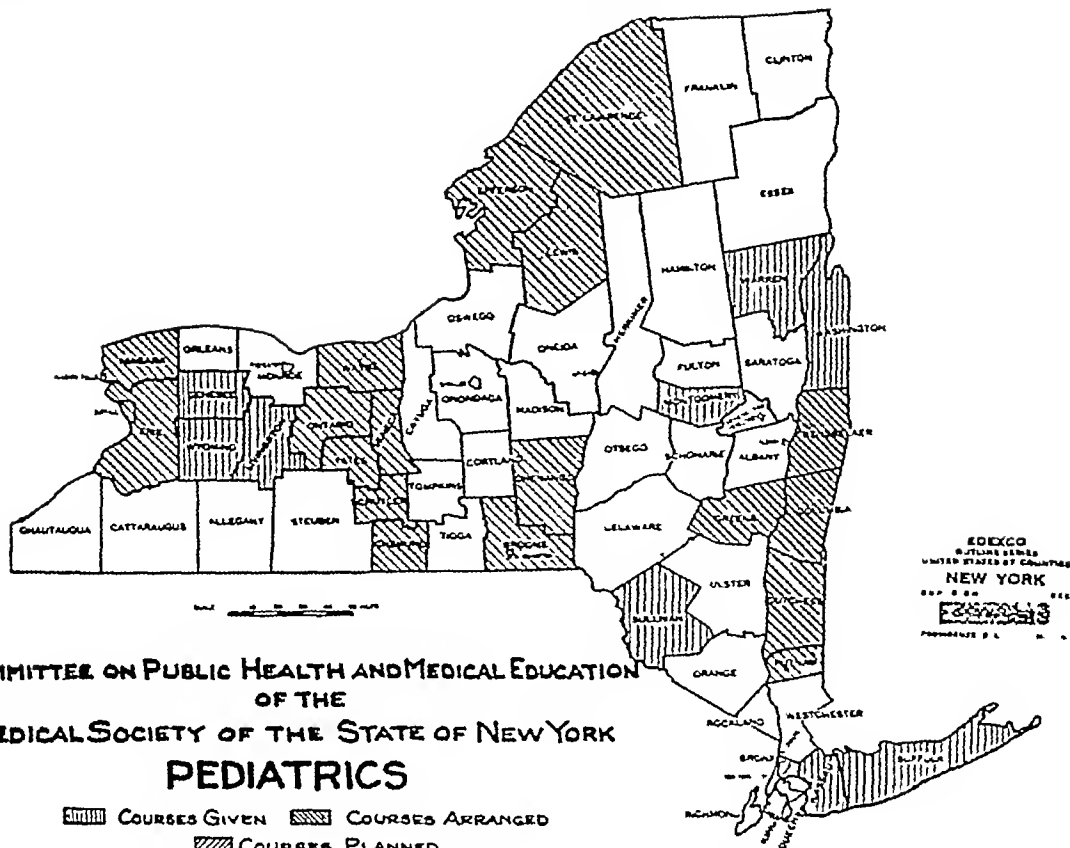

1925 RECEIPTS AND EXPENSES, EXCLUSIVE OF STENOGRAPHERS' SALARIES AND INCIDENTALS

RECEIPTS	
Advertisements and sales	\$8,637.50
EXPENSES	
Printing, Postage and Delivery	12,401.77
Commissions	1,146.25

Respectfully submitted,
E ELIOT HARRIS, Chairman

March 15, 1926

Comments on the JOURNAL were made by the President and were approved by the Reference Committee and the House of Delegates See page 420

our Committee Only in this way can arrangements for a large number of courses be made effective in a reasonable length of time The service and warm co-operation of the State Department of Health has been invaluable

Courses in obstetrics have been given in the Counties of Jefferson, St Lawrence, Chemung, Steuben (Hornell), Fulton, and Herkimer, and arrangements have been definitely made for the Counties of Cattaraugus, Chautauqua, Clinton, Franklin, Essex, Nassau, Orange, Otsego, Schoharie, Rockland, Warren, Washington, and Ulster Dates are not yet set, but courses will probably be given in Albany, Tioga, Steuben (Corning), Cortland, Tompkins, and Orleans

Courses in pediatrics have been given in the Counties of Suffolk, Washington, Warren, Genesee, Livingston, Wyoming, Sullivan, and Nassau, and courses are definitely arranged for the Counties of Broome, Chenango, Chemung, Steuben (Hornell), Schuyler, Dutchess-Putnam, Columbia, Greene, Jefferson, St Lawrence, Lewis, Niagara, Erie, Ontario, Wayne, Seneca, Yates, and Rensselaer Arrangements are being made for Albany, Saratoga, and Steuben (Corning)

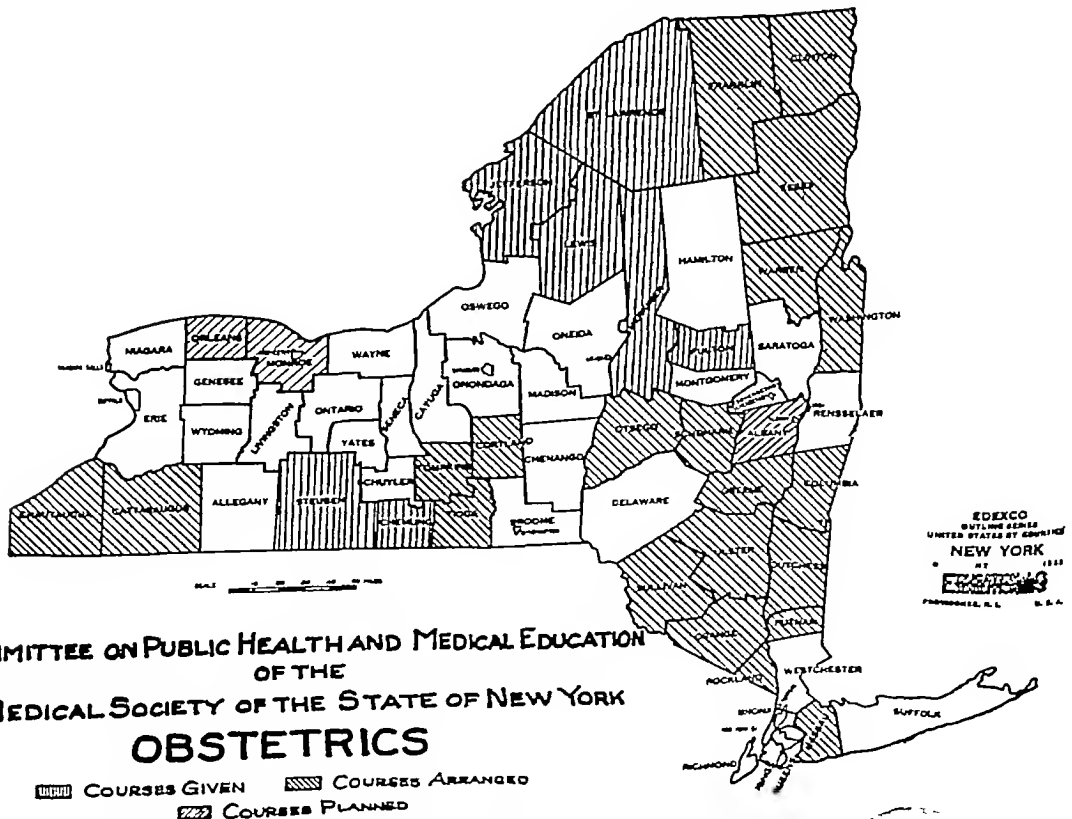

From various sources we have compiled a list of men willing and able to teach, and from this group we have provided single talks, or groups of talks, and clinical demonstrations for the Counties of Allegany, Montgomery, Sullivan, Suffolk, Orange, Otsego, Dutchess-Putnam, and

Nassau In a general way these topics covered heart, kidney, skin, hernia, tuberculosis, congenital syphilis, gastro-enterology and pediatrics. We have numerous requests for special clinics, lectures, and courses, and we have supplied the demand as far as possible We prefer, however, to provide speakers for times apart from regular county society meetings, hoping to supplement rather than supplant what the society has been doing

In our spring program a course on Diseases of the Chest has been arranged for Saratoga, a course on Nephritis and Hypertension for Oswego and Onondaga, a course on Nephritis, Diabetes and Hypertension for Montgomery These courses will also be available for other county societies

In November, 1925, we mailed to every member of the State Society a copy of the A M A Manual on Periodic Health Examinations This was a new edition of 12,000 copies with a special cover stating that "The Committee on Public Health and Medical Education of the Medical Society of the State of New York presents to every member of the State Society this Manual as one feature of its General Program for Health and Education" The suggestion of the Committee that the A M A undertake this State wide method of distribution has caused other states to follow our example

We have prepared an exhibit for the annual meeting of the Medical Society of the State of

REPORT OF COMMITTEE ON LEGISLATION

To the House of Delegates

GENTLEMEN

Your Committee on Legislation begs leave to make the following report

During the late summer and fall the Committee made the usual preparations by informing itself as to the names of the chairmen of the Legislative Committees of the County Societies, the personnel of the legislature and also, through communications, endeavored to learn how Medical Societies in other states conducted their legislative work. Some exceedingly interesting and valuable suggestions were received from other states, particularly endorsing an idea that we were considering with favor, that of stimulating cooperation with lay organizations having an interest in health matters. We were informed that a program in which welfare and civic organizations took a part, has been particularly effective in California, Washington and Oregon during the last five years.

Since the principal legislative interest that we were to have during the coming year was the enactment into law of an amendment to the Medical Practice Act which was being prepared by the Special Committee appointed in accordance with the wishes of the House of Delegates and the enactment of an amendment to the Workmen's Compensation Law along the lines taken by Assemblyman Miller's medical bill of last year, we began such activities as we thought might bring about a cooperative interest from certain welfare organizations, particularly the State Charities Aid Association, which, through its County Committees on Tuberculosis and Public Health, exerts a powerful influence for advancement of health in every community throughout the State.

We were surprised to find that many lay groups were eager that our amendment should be enacted and a number of civic organizations willingly studied our program and have since lent us their support.

After the Committee's amendment was accepted by the Council and the State Department of Education, we were encouraged through our contacts in the legislature to believe that our efforts this year would meet with success. The chiropractic bill, on the other hand, did not seem this year to bring out as much interest as in previous years. Hearings on the two bills were arranged for separate days. We thought this advisable, because it prevented a confusion of the two bills which seemed to prevail in past years and to have been encouraged by the chiropractors. This year the chiropractors were obliged to speak of the merits of their own bill and did not have the opportunity of spending all of their time in denouncing the Medical Practice Act. This analysis brought out the fact that the

chiropractors did not have a very strong constructive argument, while on the contrary, at the hearing of the Medical Practice Act, the discussions were of an unusually high plane and markedly constructive in character.

The Assembly Public Health Committee has reported out the Medical Practice bill and the Esmond chiropractic bill and probably by the time this report is submitted, the Assembly will have taken action on these two bills. The bills are a little slower in coming out of the Public Health Committee in the Senate, but will very likely be before that Chamber by the time this report is read.

The influence of activity on the part of the lay organizations is quite evident in the Capitol. Long petitions are being received by legislators, signed by hundreds of prominent laymen, requesting favorable action on the Medical Practice Act. Legislators report that the demand for the enactment of the chiropractic bill has markedly fallen off since last year. Another influential organization that has come to our assistance this year is the American Association for Medical Progress, whose director appeared with a very powerful argument at the hearing of the chiropractic bill.

Our Trustee Bill had an uneventful career, it passed the Assembly first and finally the Senate, and has gone to the Governor for signature at this writing. Another bill in which we have a vital interest is an amendment to the General Laws, providing regulations for the establishment and conduct of nurse registries. This bill was introduced in the Assembly within the last ten days.

There has been the usual number of fantastic bills presented this year, among them are two chiropractic bills, two drugless therapy bills, the chiropody and optometry bills requesting the privilege of using the title "doctor", a bill asking for the licensing and organization of manufacturers of splints, a bill calling for organization and licensing of hairdressers, the usual sheaf of amendments to the Workmen's Compensation Law appeared and most of them will be dropped in Committee. Probably few changes in the Workmen's Compensation Law will be authorized this year. The legislature seems to be inclined to appoint a Commission to study the Workmen's Compensation Laws and other labor laws, in order that in another year the amendments may be introduced in accordance with some constructive program. It is quite possible that the Miller medical reorganization bill will be laid aside until this Commission's report is submitted.

Bills with a socialistic tendency were not wanting. The health insurance bill of four years ago was reintroduced, but got no farther than the Committee in the Assembly. A bill providing that all school children's eyes should be examined

interest in the question as a whole and a sincere desire to help solve the problem. The Chairman of the Committee made contact with many doctors, some more and many less familiar with workings of the Compensation activities, in an endeavor to secure every possible viewpoint on the subject.

After securing a composite picture of the minds of the profession on the whole problem, and sensing a definite, decided expression for immediate relief, the Chairman of the Committee felt the urge to attempt to put into form for legal enactment, those suggestions which lend themselves to such uses. A tentative bill was formulated, incorporating all the important provisions that were felt to be necessary in a constructive amendment to the Compensation Law. Copies of the tentative bill were then sent broadcast throughout the State with an invitation for constructive criticism. There was a gratifying response to this invitation. Many of the doctors to whom copies of the letter and bill were sent were good enough to say that the issues were so sharply and accurately defined that we should lose no time in putting them into form for specific consideration, and, after they had been altered or amended in conformity with the suggestions and criticism of the profession, they should be presented to the legislature. This suggestion was favorably considered because of its many constructive, progressive possibilities. A meeting of the Special Committee appointed by President Van Etten was called at Syracuse. The tentative bill as drafted was thoroughly considered and adopted as the suggested modifications of existing Compensation Law, and this report sent to the members of the Council through Dr. Britt, with recommendations that they take immediate steps to introduce this bill in the legislature. Probably the outstanding idea in the mind of the Committee as to the effect that would be obtained, and which they desired in the introduction of this bill, was the criticism it would receive and the opposition to it that would be shown. These results furnished your Committee would be added, necessary, and essential information that would aid you in outlining future activities along this line. It was thoroughly understood by men of experience that there would be no possibility, nor was there any wish for the passage of this bill during this legislation session. The first complete draft of the bill was introduced by Representative Miller and Senator Truman.

Dr. Shaw, Chairman of the Legislative Committee, was especially helpful to the Committee in forwarding to the Chairman certain suggestions which he felt necessary to perfect the bill from the standpoint of a physician. The necessary changes were made to meet these points and the bill, in its final draft, was presented by your Chairman at the conference of County Legislative Chairmen held in Albany, February 10th.

This conference unanimously voted to recommend the support of this bill by the State Medical Society.

During the months that this problem has been studied by your Committee, the Chairman, Dr. Hourigan, has had many invitations to address the County Medical Societies on the subject of the proposed bill. It was physically impossible to accept all these invitations. He was able to accept invitations from the County of Erie, Monroe and Oswego, and these Societies have gone on record as unanimously in favor of the measure.

On February 24th, a hearing was held before the joint Committee on Labor and Industry of the Senate and Assembly on this bill. As evidence of the interest aroused in the whole subject of Compensation and the various bills presented, was the large attendance at this hearing necessitating the use of the Senate Chamber to accommodate all those who appeared. Several members of your Committee made a perfunctory appearance before this Committee, offering only sufficient explanation of the bill to draw the fire of the opposition. The great value of this hearing to your Committee lay in the fact that representation of the opposition to this measure voiced specific objections. The objections presented at this hearing convinced your Committee that there is no real argument against the proposed measure that is based on its merits. The speakers in opposition used only the argument that the medical profession were attempting to make themselves final authority on medical questions. Far from being a real objection to the bill this constitutes the main vital reason for formulating such an amendment to the Compensation Law. This bill would endanger the dominant position of certain vested, predatory interest which have entrenched themselves through long years of administration of the present Compensation Law. This condition has been made possible by the supine attitude of the medical profession in its relation to a problem which is of vital interest. We would definitely and urgently avow any desire to force our ideas upon the profession. The State Medical Society for years has appointed Committees to study this problem, the last two of which Committees have reported back to the House of Delegates their inability to reach any solution of the problem. Your present Committee felt that it was of the utmost importance that some definite, concrete legislation be brought forward, not with the idea of having such legislation passed at this session but recognizing the fact that the profession of the State as well as other interests concerned are badly in need of education on the whole problem of the Workmen's Compensation Law. The bill drafted by your Committee and now before the legislature, is only a step in the right direction of eliminating undesirable provisions of the present law. We feel that the first fundamental principle to be

by optometrists appointed by the Boards of Education, and another bill which would supply all children with eye glasses free of charge will both likely remain in Committee. The anti-vivisection bill has appeared within the last two or three days. The amendment is limited this year to preventing experiments upon living dogs.

The birth control bill has not yet appeared.

Your Committee wants particularly to express its appreciation of the cooperation received from the County Chairmen. The attendance at the conference of County Chairmen was practically as extensive as last year, regardless of the fact that one of the worst blizzards of the season was raging in the southeastern part of the State on that day. We would suggest that County Societies make some effort to have the information which we sent out through our weekly bulletins, spread among their members. We were amazed several times during the winter to have physicians tell us that they knew nothing about what was going on at Albany, they did not even know that the State Society was particularly interested in an amendment to the Medical Practice Act. It would seem to us that the County Societies could probably arrange for one or two special meetings during the time of the session of the legislature, for the purpose of hearing from the local chairman of the Legislative Committee what is transpiring at Albany. Such program would prevent one Society from getting out of step with a ma-

ajority of the Societies in supporting or opposing proposed legislation. It is exceedingly difficult, if not absolutely impossible, in matters of legislation, to foretell what one's attitude will permanently be toward any but the most vicious bills, because in many instances the bill as originally drawn does not exactly meet the wishes of its author and opposition may justifiably be expressed to the bill at that time, but after a hearing or after conversation with its opponents, the author may amend the bill so as to remove the objectionable features and thereby win the support of its early opponents. Unless the individual physicians of the County Society have a way of learning from the chairman of their local committee about such amendments, their activity in support or in opposition may be wide of the point through their ignorance.

It is with great pleasure that we also speak of the splendid cooperation we have had from Senator Karle and Dr. Lattin, chairmen of the two Committees on Public Health, and from Senator Webb, Assemblyman Loomis and Assemblyman Miller who are sponsoring our bills in the separate Houses and enthusiastically working for their enactment.

Respectfully submitted,

HENRY L. K. SHAW,
Chairman

March 20, 1926

The Reference Committee and the House of Delegates approved the plan of the Committee on Legislation by which lay organizations were enlisted in the active support of the Practice of Medicine Act. The successful passage of the Act by both Houses of the Legislature is further evidence of the wisdom of securing their support. See page 465.

REPORT OF SPECIAL COMMITTEE TO STUDY THE WORKMEN'S COMPENSATION LAW

To the House of Delegates

In submitting the following report of the "Special Committee appointed by the President, Dr. Van Etten, to study all laws affecting Workmen's Compensation and to suggest modifications on existing Compensation Law," your Committee feels that a brief outline of the work of the Committee will be of interest and value to the House of Delegates.

Upon receipt of the appointment to the Chairmanship of this Committee, my first inclination was to follow the example of previous committees appointed for this purpose—that is, recognize it as a very difficult, impossible job and pass it up. After several conferences with Dr. William Britt, Chairman of the Committee on Economics, State Society, I decided, however, to take the plunge and attempt the task delegated to me by President Van Etten. A letter was written to Dr. Van Etten, a copy sent to Dr. Dougherty, President

and Secretary of the Society, acquainting him with this decision and setting forth certain suggestions in connection with the Workmen's Compensation Law and relationship of the Medical Profession to it, and definitely outlining points to be considered.

The first week in December, a conference of Dr. Van Etten and several members of the Committee, who happened to be present at the State Industrial Safety Conference in Syracuse, was held, and it was decided that twenty-five copies of this letter be sent to each member of the Committee for distribution among his doctor friends, and several hundred copies to be distributed throughout the State. The purpose of this was to secure reaction, criticisms, suggestions, in order to know the attitude of the members of the Society.

The reaction to this letter was most striking and most encouraging to your Committee. Letters from all over the State evinced the greatest

"Thus it appears that after 22 years of operation of the registration law of the State of New York many institutions are woefully short in supplying the minimum necessary educational facilities for turning out Registered Nurses from their own training schools. As trained nursing is so important an adjunct to the profession of medicine not only in the care of the sick but also in maintaining the health of the people by preventive measures, as the hospital is instituted primarily for the care of the sick and not as an educational institution, and as hospitals find difficulty in providing funds for the proper establishment and support of registered training schools, and as nurse training now has become strictly an educational activity, it would appear that the time has arrived completely to separate the training school from the hospital, notwithstanding that hospital experience is of paramount necessity in the education of nurses.

"I offer as a substitute for the present system of nurse training that the Department of Education of the State of New York take over entirely nurse education by establishing in its vocational schools nurse training as an extended high school course, that the course begin with entrance to the high school and extend for a period of from five to six years, at least one or two of which shall be spent in residence in and in training in an approved hospital before granting the certificate of Registered Nurse licensing the holder to practice as registered nurse in State of New York.

"I have not worked out the details of such a scheme but have worked out Tables A, B, C, and D, showing hours spent and curricula. Practical teaching could be obtained by arrangement with home institutions for non-resident pupil-nursing service. According to the October, 1923 issue of the American Hospital Digest and Directory there were in the State of New York 617 hospitals and sanitariums with a bed capacity ranging from 3 to 6,537 making a total of 121,084 beds. In addition there were 91 allied institutions taking care of infirm, abnormal or chronically sick people with a bed capacity ranging from 2 to 400, making a total of 5,362 beds.

"These 708 institutions with 126,446 beds, are scattered throughout New York State and so located that high school girls taking nurse-training vocational courses could be given non-resident elementary experience in the care of the sick and unfortunate at the very doors of their homes, a practical and efficient substitute for the four months probation in preliminary course, a great expense to hospital as well as a substitute for the 'trained attendant' schools.

The teachers would be licensed, appointed and paid by the State which would relieve the hospitals of a great financial burden.

The Qualifying hospital would secure under-

graduate resident service covering an average of 12 to 22 months from each more or less well prepared pupil in return for the clinical facilities offered the State for Training purposes. The pupil nurse labor-turn-over, about 50% of the annual registration, would be reduced to a negligible minimum. The hospital only would have to supply domicil for one-half to one-third the number of pupils for which it now provides, thus leaving more space for hospital beds or other activities, while the waste, wear and tear of hospital supplies very greatly would be lessened,—another reduction of expense.

"I feel that the quality and quantity of classroom work under such scheme would be above criticism even from the most sensitive physician. There would be no necessity for other qualifying names.

"I feel that the number of properly qualified nurses turned out under this scheme would meet all the demands of the practice of medicine and of hospital requirements.

"I believe this scheme also provides a proper stepping stone for entrance to university instruction to secure bachelor degrees in nursing, from which graduate personnel teachers of nursing, public health nurses, etc., might be drawn."

Periodic Examinations of Apparently Well People is a question that is attracting the widespread attention of the Medical Profession of this State, especially the general practitioners. Through the efforts of your committee a program was put on at the Eighth District Branch meeting in October showing how to carry this message to every member in each County Society and thus with the work being done by the Committee of Public Health and Post Graduate Education bring something of real value to every member of Organized Medicine who is willing to avail himself of the opportunity.

As a sample blank we submit the following which was adopted in Erie County. (See sample enclosed)

We recommend that each District Branch act as a sort of Clearing House for the ideas and problems that should be carried out in every county in their district.

Workmen's Compensation. We feel that the State Society is especially fortunate in the selection of Dr. P. Hourigan of Buffalo as chairman of a special committee to study the Workmen's Compensation Law.

His twenty-five years experience with the medical problems of industry and his high ideals of the practice of medicine, his intimate association with the workings of the Workmen's Compensation Law since its inception and his earnest desire to have medical problems solved by medical men make him especially well qualified to handle this vast question.

recognized in the Compensation Law is that there are three principle parties to the whole question—namely, the workman, the employer and the doctor. No equitable administration of a compensation law to properly benefit the workman can be secured without the most expert medical service available. Your Committee believes that the medical profession cannot aim too high in its efforts to secure recognition of this fact.

It follows as a natural corollary that organized medicine should be held responsible for the character of work done by its members in the administration of this great and beneficent Compensation Law by the creation of a State Medical Advisory Council and of District Medical Advisory Councils, the personnel of which must be approved by the State Medical supervision of its particular work under the law by providing for the appointment as Medical Director and Deputy Medical Director a man who shall be satisfactory to the State Medical Society as a body. The highest standard is established in the medical administration of the law.

A very important, if not the most important, provision of the bill is that whereby the problem of conflict of medical evidence is solved by the reference to a medical expert appointed by the State Advisory Council.

Finally, your Committee is in a position to know that such advanced legislation as contemplated in this measure will fail of enactment in this session of the legislature. In fact, the friends

of this movement, in watching its progress, have moved in a way to prevent the passage of this bill at this session, in order to give the members of the Medical Society of the State of New York, every opportunity to give expression to their ideas and wishes. The work started by your Committee should be continued until all parties concerned are brought to the position of recognizing the contention made by your Committee that no one but the most competent doctors should assist in the administration of the medical provisions of the Workmen's Compensation Law or decide the important questions of medical problems. The repellent methods now pursued, which have resulted in many of the best type of doctors of the State refusing to touch compensation cases, can only be corrected by radical changes in present practices. The injured workman should receive the best possible service that organized medicine can give and this end can be best attained by the Medical Society of the State of New York taking a live, active interest in the detail workings of the medical provisions of the Compensation Law.

This task has taken a great deal of physical energy, time and money, and the chairman, feeling that he has contributed his share, wishes to express an insistent desire to be relieved of any further activity in this work.

Yours very truly,

P. H. HOURIGAN, M.D., *Chairman*

March 29, 1926

The Reference Committee on Legislation, in discussing the proposed Workman's Compensation Acts, said, "The problem has not been solved—it calls for re-statement and re-solution." Pages 458 and 465.

REPORT OF COMMITTEE ON MEDICAL ECONOMICS

To the House of Delegates

GENTLEMEN

The work of the Committee on Medical Economics this year has been directed toward assisting movements already under way.

A Questionnaire to each county society early in the year showed that the following questions were considered of the greatest importance:

- 1 The Nursing Problem
- 2 Periodic Health Examinations
- 3 Workmen's Compensation
- 4 Industrial Medicine

We have directed our efforts toward the consideration of these questions this year.

The work on the Nursing Problem has been in conjunction with the Special Committee to study this problem and as the work of that committee has been so wide spread and constructive and seems to offer a means of solving the most of that problem we do not care to bring in separate report. As chairman of the economics com-

mittee I should like to see more emphasis placed on the plan of Doctor Lytle as revealed at the Utica Conference, his suggestion is as follows:

"On January 1, 1925 in the State of New York there were upwards of 150 institutions conducting nurse training schools. The Regents register 143 of these institutions as maintaining acceptable training schools. However, only 22 of these recognized institutions gave the complete required training within their own walls. To complete the required training the other schools affiliate with institutions giving training in the lacking topic. There is a diversity of opinion regarding the effects of this procedure. However, the Board of Regents require that all educational institutions seeking its recognition and endorsements shall comply with the minimum requirements so that individuals contesting the Regents' examinations for certificates or licenses shall have a minimum standardized preparation, and so that the public which include the practicing M.D., shall be protected.

It would seem wise in these days of specialism and near specialism that the Society of the State of New York, made up very largely of general practitioners, should conclude its Annual Meeting with a session in which the unity of disease should be strikingly emphasized and the necessity of a broad clinical viewpoint clearly demonstrated.

Osler said "I often tell my students that it is the only disease which they require to study thoroughly. Know Syphilis in all its manifestations and relations, and what remains to be learned will not stretch the pia mater of a mega-locephalic senior student."

The Committee has therefore striven to present this subject on Thursday, April 1st, in a way which will be most helpful to every member of the Society no matter what his field of practice. The morning session will begin with a complete clinical and pathological demonstration of every phase of Syphilis illustrated by patients, pathological specimens, moving pictures (10 machines constantly in operation) charts, instruments, drugs, etc. This demonstration will continue the entire day and will be in charge of the leading syphilographers of New York City who will be in constant attendance to demonstrate characteristic lesions, to clear up questions of differential diagnosis and to indicate the accepted lines of treatment in the difficult phases of this disease. In fact they will stand ready to answer in the light of our present knowledge all questions in regard to Syphilis.

In the afternoon there will be seven fifteen-minute addresses without discussion on the leading phases of Syphilis by outstanding authorities of this country.

2 00 P M—"What Price Syphilis?" By William F. Snow, M.D.

The Reference Committee and the House of Delegates especially commended the entire program of scientific work. "The special day's program on syphilis deserves the hearty support and attention of the whole Society." Page 463

REPORT OF THE COMMITTEE ON ARRANGEMENTS

To the House of Delegates
Gentlemen

The Committee on Arrangements takes pleasure in saying that all arrangements have been made for the coming Annual Meeting which will be held at the Waldorf-Astoria.

The Waldorf-Astoria, as every one knows, is

*2 15 P M—"Syphilis from the Point of View of the Dermatologist" By Grover Wende, M.D.

2 30 P M—"Syphilis from the Point of View of the Internist" By Udo J. Wile, M.D.

2 45 P M—"Syphilis from the Point of View of the Neuropsychiatrist" By George F. Kirby, M.D.

3 00 P M—"Syphilis from the Point of View of the Obstetrician" By Alfred C. Beck, M.D.

3 30 P M—"Problems, Methods and Results in the Treatment of Syphilis" By John H. Stokes, M.D.

This remarkable and unique presentation of probably the most historic and virulent disease in the world was possible only by the co-operation of the resources of the New York City Department of Health, New York State Department of Health, New York State Hospital Commission, New York State Department of Charities and the American Social Hygiene Association. Our thanks are especially due to the splendid work and efficient organization of our local Committee of which Dr. Louis I. Harris of New York is Chairman. They have spared no effort and no exertion to make this demonstration so attractive and valuable that no member of the profession could afford to miss it.

Respectfully submitted,

ANDREW MACFARLANE,

March 15, 1926

Chairman

* Dr. Grover Wende was killed by an automobile February 9. His death was almost an irreparable loss to his community and profession. He was an outstanding personality in our Society and very generously accepted this invitation to take part in the symposium. Dr. Jay Frank Shamberg has kindly consented to take his place.

particularly well arranged for meetings, as most of the rooms are large and give ample space for the Scientific Sessions, which promise to be of usual interest at the coming meeting.

We are fortunate in being able to hold all the meetings on one floor, including the House of Delegates, Scientific Sessions, Bureau of Regis-

His committee while not organized until November did some very rapid work and as a result of the replies to hundreds of letters sent to individuals and to every County Society in the State he prepared a bill which was introduced at the opening of the legislature on January 4, as A165, SI35

This bill has been approved in the main by every County Society meeting at which it was presented and by the Conference of Legislative Chairmen at Albany on February 10. We feel that the enactment of this bill into law will go a long way toward the solving of some of the problems of the Workmen's Compensation Law and at the same time place greater responsibility on the Medical Society of the State of New York.

We recommend that the present Special Committee to study the Workmen's Compensation Law be continued another year and that the present House of Delegates approve their work thus far.

Industrial Medicine Your committee has felt that Organized Medicine was losing something that the fellows in Industrial Medicine were enjoying. The live bunch of fellows who constitute the New York State Society of Industrial Medicine have done some real constructive work. We feel that it would add very much to the strength of Organized Medicine if the Industrial Physicians would put on one of their splendid programs as a separate section of the State Program next year. We feel that this could be done without in any way detracting from the strength of the New York State Society of Industrial Medicine.

Your committee this year participated with the committee on arrangements for the Ninth Industrial Safety Congress. With the co-operation of the President and Secretary of the State Society there was a closer union of the State Society and Industrial Commission than ever before.

Your committee has felt that personal conferences lend much to a cleared understanding of the problems confronting the Medical Profession. As a result your chairman has had the privilege of discussing the forementioned problems before the Society meetings or the Economic Committee in several counties throughout the State.

We feel that the combined effort of the State Department of Health, State Charities, and the Medical Society of the State of New York to work together for the eradication of diphtheria by 1930 is a progressive step that should enlist the support of every physician in the State.

We realize that the work done this year is but an infinitesimal part of the vast work to be done, but we offer it and thank you for the opportunity.

Respectfully submitted,

WILLIAM WARRLEN BRITT, M D, Chairman,
CHARLES O. BOSWELL, M D,
NELSON K. FROMM, M D,
HENRY B. DOUST, M D,
ARTHUR S. CHITTENDEN, M D

For an action on the suggestions regarding Workingman's Compensation, see the report of the Reference Committee on Legislation, page 465.

REPORT OF COMMITTEE ON SCIENTIFIC WORK

To the House of Delegates

GENTLEMEN

This Committee has had two sessions. The first at the Princeton Club, New York City, on Sunday, November 29, 1925, when the entire Committee together with several secretaries of the sections and the Chairman of the Committee of Arrangements, Dr. E. R. Cunniffe, met and discussed in detail the general topics which should be presented at the Annual Meeting of the Society.

The second and final meeting was held on February 7th at the Waldorf-Astoria. The entire Committee was again present together with Dr. E. R. Cunniffe and the general manager of the Society, Miss Baldwin. After a complete dis-

cussion and acceptance of the programs of the sections, an adjournment was taken to inspect the rooms where the sessions of the sections were to be held. The requirements of each section were then fully considered and discussed.

The three years' experience of the Chairman has emphasized the wisdom of holding the meetings of this Committee on Sundays when it is possible to secure a full attendance of the Committee.

On account of the very great success of the Thursday session on Tuberculosis at the last Annual Meeting in Syracuse, N. Y., it was decided to test out at this meeting in New York the same general plan and to consider Syphilis from every point of view.

It would seem wise in these days of specialism and near specialism that the Society of the State of New York, made up very largely of general practitioners, should conclude its Annual Meeting with a session in which the unity of disease should be strikingly emphasized and the necessity of a broad clinical viewpoint clearly demonstrated.

Osler said "I often tell my students that it is the only disease which they require to study thoroughly. Know Syphilis in all its manifestations and relations, and what remains to be learned will not stretch the pious mater of a megalopcephalic senior student."

The Committee has therefore striven to present this subject on Thursday, April 1st, in a way which will be most helpful to every member of the Society no matter what his field of practice. REPORT OF SPECIAL COMMITTEE ON NURSE QUESTION

To the House of Delegates

Gentlemen

At the annual meeting of the House of Delegates held at Syracuse in 1925, a report of a Special Committee on the Nurse Question was presented. On account of the great importance of the subject, and the fact that no definite plan or scheme had been advanced as a possible solution, the House of Delegates voted that the incoming President appoint a Special Committee to continue the investigation and to submit its findings to the 1926 annual meeting of the Society.

The salient facts and data relative to the general scope of nurse education contained in the 1925 report, have been confirmed and are accepted as established facts without repetition in this report.

For the purpose of a survey, the committee was subdivided into two groups—the lower half of the State, under the chairmanship of Dr. E. Eliot Harris, and the upstate under the chairmanship of Dr. Andrew Sloan.

The committee as a whole, and as subcommittees held several conferences with interested groups of citizens, including Nurse Associations, Hospital Superintendents, Board of Hospital Managers, several prominent physicians and representatives of the State Education Department.

We submitted pertinent questions in advance to all of these groups as a basis for conference discussions. The subjects proposed for discussion were substantially as follows:

(A) Present standards of Nurse Education including preliminary requirements

(B) Length of time required to train a nurse

(C) Cost of training a nurse

(D) The ultimate distribution of graduates into bedside nurses and the higher activities relating to Public Health, School, Red Cross, Teaching and Industry

(E) Constructive criticism and suggestions pertaining to the economics of the Nurse Question

Owing to the complexities of this entire question and the special requirements and demands peculiar to different sections of the State, your committee discovered a wide variation in ideas

and remedies. Generally speaking, no particular group appeared entirely satisfied with present conditions, yet from the data submitted at the conferences we are unable to focus on any one or number of known factors as the definite cause for the present dissatisfaction.

The collected material, as the result of these conferences, is too voluminous to include in a report of this character. It will be filed with the Secretary of the State Society for reference by subsequent committees and interested members. Your committees can only hope to present at this time a brief epitome as a basis for our conclusions and recommendations.

PRESENT STANDARDS OF NURSE EDUCATION INCLUDING PRELIMINARY EDUCATIONAL REQUIREMENTS

The law governing Nurse Education in New York State provided for two groups:

(a) The course leading to Registered Nurse degree

(b) The course leading to Trained Attendant certificate

While it is true that definite restrictions are placed on the words "Trained," "Certified," "Graduate" or "Registered" Nurse, there is nothing in the law which prevents anyone from earning a living as a nurse. And furthermore there is nothing in the law which prevents any hospital from conducting a Nurse Training School in any way it chooses. The Education law applies solely to such hospitals as voluntarily elect to conduct Approved and Registered schools whose graduates may qualify after State examinations as Registered Nurses or become certified as Trained Attendants.

The present requirements for preliminary education leading to a Registered Nurse degree is one year of high school or its equivalent, the equivalent is determined by an expert in the State Education Department. The requirements for the preliminary education of the Trained Attendant class is a completion of the eighth grade of grammar school. As result of our survey we discovered an overwhelming opinion that these standards are not too high, and that it would be a dangerous expedient to lower them. Taking

into consideration the facts that a pupil nurse does not enter training school under eighteen years of age, and that the general education law may compel the public school pupil to continue attendance until eighteen years of age (in certain instances part-time only) in an effort to attain the eighth grade, it is reasonable to suppose that any young woman, unable to complete one year of high school or its equivalent before her eighteenth year is hardly desirable material for nurse training. She is manifestly lacking in mental equipment and ambition.

Your committee has held conferences with the State Education Department concerning the present curriculum and the distribution of the hours of study and bedside instruction. There were some individual differences of opinion, but on the whole, the course leading to a Registered Nurse degree, which has recently been revised, appeared satisfactory and necessary for the higher type of nurse provided for in this law. The State Education Department expressed its desire to continue to hold conferences with accredited committees of the State Society with the view to further revision of the curriculum from time to time.

Your committee has studied the character of questions submitted by the Board of Nurse Examiners. There were several questions, both in the written and oral examinations, which appeared to us, as physicians, totally out of place in an examination designed to determine the fitness of a nurse to practice. Obviously, if such questions constantly appear in State examinations, the pupil nurse will devote time and energy to prepare herself to meet them at the expense of acquiring more important and practical information. We have received no adequate defence or satisfactory explanation for the presence of these questions. It has been suggested that physicians, familiar with hospital teaching, should have some official contact with this Board of Nurse Examiners.

We ascertained that the number of students entering Trained Attendant Schools was not increasing but that there is a steady increase of pupils entering the course leading to the R. N. degree. The total number of pupils in Registered Schools of the State during 1925 was 6,118, an increase of 872 over the year of 1924. The average increase for the past ten years has been 194 per year. 3,651 new pupils entered the registered hospitals in 1925, whereas only 1,624 matriculated in 1920. This is an increase of 55 per cent.

LENGTH OF TIME REQUIRED TO TRAIN A NURSE

The present law requires a probationary period of four months in all cases. The minimum time of training is two years. A choice of courses is allowed covering a course of two years, two

years and nine months or three years. There are 157 Registered Nurse Training Schools in the State of New York of which only three complete their course in two years. Sixty-four give a three-year course and the others range from two years and four months to two years and nine months. Local conditions of clinical material and teaching facilities, and individual tastes in lengthening the course to include the non-required or optional subjects, are responsible for the variation in lengths of course.

COST OF TRAINING A NURSE

There appears to be no uniform system of hospital accounting, so the committee was unable to ascertain definitely the cost to the institution for training a nurse. From such data as we were able to obtain the estimated costs ranged from \$600 to \$1,300 for each nurse graduated. The burden of this expense falls either upon the endowment funds or the per diem charge to the patient. Mention should be made of the fact, in this connection, that the services rendered by the pupil nurse largely counterbalance this cost. Reduced to the basis of board, lodging and wages only, the cost of hired help, doing unskilled labor in the kitchen and ward, exceeded in all instances that of the pupil nurse. The added cost of graduate teachers, ward supervisors, laboratory equipment and nurses' homes—all very necessary and desirable features, amounts to a very considerable sum and one which is bound to increase greatly the general expense of the hospital.

A study of the ratio of students to patients in 110 registered hospitals in New York State, having a total capacity of 15,769 beds, shows the interesting facts that the ratio is one nurse to two and a half patients in hospitals of 50 to 150 beds, one nurse to three patients in hospitals of 150 to 300 beds, and one nurse to four patients in hospitals having 300 or more beds. This explains in part the relatively higher cost of maintaining a training school in a moderate size hospital.

In reply to our inquiry, "Why do you conduct a Nurse Training School?" some very frankly said, "In order to provide nursing help in the hospital," and others said, "As a matter of benefit to the community." It is our opinion that both the utilitarian and altruistic motives are responsible in all cases.

THE DISTRIBUTION OF GRADUATES

Notwithstanding the steady increase in the number of young women entering training in the hospitals of New York State, an increase of 55 per cent within the past five years, the ratio of demand for skilled nurses exceeds that of the visible supply. Broadly speaking, there is a demand for two general types of nurses, one, a strictly bedside nurse willing to respond to the

call of the sick, either in the private home or the private room of the hospital, and the other, functioning as a nurse in the activities of Public Health, Public School, Red Cross, or Nurse Teaching

From the statistics and opinions gathered at our conferences, we learned that there is not only a dearth of the bedside type, but of the other group as well. According to the 1925 State census, there were 19,678 graduate trained nurses in the State—a ratio of one to every 567 inhabitants. We were unable to determine what percentage of these were attached permanently to sanatoria and health resorts and what percentage were in the higher activities of Public Health, etc. Approximately 15 per cent of Registered Nurse graduates ultimately take up work of the latter type.

A study of distribution made by the State Education Department shows that in a certain few rural counties the ratio of nurse to population is one to four or five thousand. In a few counties the ratio is one to two or three thousand, while in New York County the ratio is one to 282, indicating that the nurses concentrate in the centers of population and wealth. Both graduate and undergraduate nurses are included in the above.

For the entire State there is one nurse to every 432 of the population. This includes nurses in training.) A similar study, based on the 1920 census, shows the identical proportion, from which can be deducted the fact that the relative proportion of nurses to the population has not increased at all in the past five years.

The shortage of bedside nurses is not strictly speaking seasonal, but appears at varying times in different years, and is not manifested synchronously throughout the State. In all localities there are times when the registries have several nurses waiting on call.

We were told from the hospital superintendent group that, within three or four years after graduation, many nurses are lost to the profession, frequently through marriage and occasionally through ill-health or because of a decision to go into some other field of work. This same superintendent group doubted whether it were ever possible to supply a sufficient number of trained nurses to meet all present-day demands.

Through the system of annual registration of Registered Nurses, we know that 19,678 nurses were practicing in the State of New York on January 1, 1926, in some capacity. In addition to these, there is a large number of young women assuming the rôle of trained nurse. Many of these have come from other states, having graduated from institutions not accredited by the New York State Education Department as meeting the minimum standard required by law. According to this same law they are not entitled to use the

term "Trained," "Graduate," "Certified" or "Registered" nurse, and by that same law they can not assume the supervisory positions in hospitals conducting Training Schools under the supervision of the State Education Department. Laws in other states militate against foreign nurses who have not met local standards in much the same way. The theory of the New York State law is to protect the graduate of our own registered hospital group, and to prevent graduates of presumably inferior institutions in other states from coming into direct competition with the New York State Registered Nurse.

It is alleged that the commercial nurse registries supply nurses without discrimination as to their status. There can be no objection against the practice of supplying nurses of any type in case of great urgency or stress of epidemics, but it seems to be the consensus of opinion, gleaned from our conferences, that under normal conditions all nurses sent out on cases should be properly labelled, so that the family and physician might be informed whether the nurse were a bona fide registered nurse, trained attendant, graduate nurse unrecognized in this State, or practical nurse. To correct this condition a movement has been started to establish in each city an official registry, conducted by a selected number of physicians, registered nurses and interested laymen. Such an official registry is now established in Buffalo, and just passing beyond the experimental stage. The Official Registry should have the hearty co-operation of all physicians and nurses interested in solving one of the many perplexing problems of the Nurse question.

ECONOMICS OF THE NURSE QUESTION

The economic advantage to a community of highly trained nurses is often overlooked by those who are so urgently insisting upon a lowering of present standards by way of stimulating the production of strictly bedside nurses.

Undoubtedly the work of the Public Health nurse is instrumental in forestalling a great amount of sickness through preventative measures and intelligent instruction of the masses on health and hygiene. The necessity for highly trained women to supervise departments and instruct classes in hospitals is obvious. The present methods of obtaining these is to require the registered nurse to pursue a post-graduate special course. Manifestly whatever changes may be suggested in our system of nurse education, provision must be made for a continuance of the present program of educating nurses in hospitals, leading to an R. N. degree.

Contrary to the opinion sometimes expressed, all Registered Nurses do not go into the higher activities, but many remain as very superior bedside nurses throughout their career.

It already has been mentioned that the expense

of maintaining an Approved or Registered Hospital is so great as to become prohibitive for many hospitals whose value and necessity in their respective communities is unquestioned. These institutions have left to them the alternatives of either employing graduate nurses to run their wards and departments, or to conduct training schools whose graduates can not hope to register as Trained Nurses, or ever be recognized as such in this State. These Institutions find the greatest difficulty in securing pupils for training on this account.

In view of the fact that there is an all too apparent need for more nurses of the bedside type, our conferences discussed the desirability of establishing a course of training particularly suitable for this type and one which could be provided at comparatively small cost by a number of hospitals unable to conduct a Registered Training School of present standards.

This course, for lack of better name, was called the Basic Training Course, to include only the absolute essentials of anatomy and physiology, hygiene, materia medica, obstetrics and gynecology, internal medicine, pediatrics, dietetics and surgery. The didactic lectures to be minimized and particular stress laid upon bedside technique. The entrance requirements suggested were at least one year of high school or its equivalent, and the course at least twenty months preceded by four months probationary period.

A young woman passing through such a course should have a title consistent with the training. It was suggested that she might very properly be called a "Hospital Graduate Nurse."

The details of this plan require further study and your committee is not yet prepared to present a final program. The essentials of this plan were presented at a conference of hospital superintendents and prominent registered nurses and met with hearty approval. The State Education Department expressed a willingness to entertain the idea.

The question of part-time and group-nursing was discussed at our meetings and we were led to the conclusion that this phase of utilizing a nurse deserves more serious thought and study by interested groups of physicians.

There is an undoubted abuse of nurse employment by the luxury loving public. This is a very serious subject and there is urgent need for reform. An instance was mentioned where one patient employed two day nurses and two night nurses. A prominent New York physician mentioned that eighteen special nurses were at that time attending patients in a strictly charity ward

of one of the city hospitals. Instances of the above kind indicate a faulty distribution and utilization of our present supply of nurses.

One of the factors not hitherto mentioned as responsible for the dearth of bedside nurses is that the occupation itself has ceased to be attractive. This was well expressed by a committee of hospital superintendents who said, "Probably some of the most important reasons for the shortage of bedside or private duty nurses are the difficult conditions under which they work, the long hours, the unavoidable loss of time, the lack of an opportunity for home life, and last and in our judgment most important, the fact that there is a constant retrogression rather than opportunity for advancement as the years go on. Younger graduates see and feel this backward trend in the tired, worn-out, middle aged private duty nurses whom they encounter in the hospitals and elsewhere, and they compare such work unfavorably with other branches which offer opportunity for advancement and personal development."

Regarding the nurses' fees and time on duty, the nurse after graduation is a free moral agent and her service to the community is controlled entirely by the basic economic law of supply and demand. No amount of legislation or regulations can arbitrarily determine her life. On the other hand, such nurses as choose to demand exorbitant terms can with justice be removed from the lists of official registries.

RECOMMENDATIONS

Your committee recommends

(A) that the Society go on record as approving the Official Nurse Registries and disapproving the commercial nurse registries so long as they fail to properly label the nurses whom they supply.

(B) that the Society approve of the suggested plan of a Basic Nurse Training Course, and that a committee be appointed by the President to confer with committees from the State Nurse Association, the State Hospital Association and the proper authorities within the State Education Department with a view of determining a suitable course of study.

(C) that the Society continue the study of the Nurse question for another year, and that the President be requested to appoint a special committee for that purpose.

Respectfully submitted,

ARTHUR W. BOOTH, M.D., *Chairman*,
March 15, 1926

MINORITY REPORT OF SPECIAL COMMITTEE ON NURSE QUESTION

To the House of Delegates

Gentlemen

As a member of the Special Committee to study the nurse problem, I find it impossible to concur in recommendation (B) "that the Society approve of the suggested plan of a Basic Nurse Training Course," as from the context I infer that it is to lead to the recognition of another type of licensed nurse in addition to those for whom provision already is made, which recognition will but increase the confusion now existing

From knowledge gained by study of the evolution of nurse education and practice since the adoption by the legislature in 1903 of the Amendment to the Public Health Law governing registration of nurses, I respectfully would submit the following as a minority report

The Regents of the University of the State of New York should receive unqualified support for insistence that the minimum nurse training education requirements demanded by law shall be maintained by each and every training school seeking their endorsement, and that such schools not only shall provide proper educational facilities but as well proper living conditions so that credentials granted by the State will represent standard minimum values. At the same time it should not be forgotten that the Regents in order to make it possible for many hospitals to maintain recognized training schools, have provided a system of affiliations so that their diplomas shall stand on an equal footing with any other recognized school. And it shall be remembered that the Regents during the twenty-three years existence of the Nurse Registration Law established several waivers, the last in 1922, whereby without passing the standard licensing examinations thousands of women whose only qualifications were that they held themselves out to the public for a period of time to care for the sick as nurses were admitted to the registered nurse ranks, this liberality, in all probability, in large measure has been the source of much of the criticism that registered nurses are "hard-boiled"

The New York State Organizations of Nurses which includes The New York State Nurses' Association, The New York State League of Nursing Education and The New York State Organization for Public Health Nursing, are to be complimented on their un-failing good nature under trying circumstances and their repeatedly expressed willingness to co-operate with the Medical Society of the State of New York, in endeavors to improve the educational and technical equipment of the professional nurse for the supreme duty of caring for the sick at the bedside, as well as

in the ever-widening field of public health activity, to improve the living and social conditions of the student nurse, that all too frequently are detrimental to her morale and preparation, to inculcate student nurses with high ideals of service, and to maintain in the heterogeneous registered personnel high ideals of service in the face of changing times and economic difficulties. The leaders of the nursing profession of the State of New York—the first State to establish hospital training schools for nurses, and, the first to standardize and license professional nurses—deserve commendation for unremitting effort to keep the Empire State in the van of progress

While it may be true that there seems to be shortage of registered nurses to do bedside nursing in the home, no such shortage seems to be found in private duty nursing in hospitals. The possible number of nurses in the field would seem to be sufficient to supply the nursing needs of the State. Investigation, however, shows the difficulty to be due to uneven distribution, a condition that has a parallel in the distribution of practicing doctors of medicine. While professional nurses have ideals of service as high, if not higher, than physicians, at the same time, like physicians, they must live, and, so like physicians gravitate to those areas in which opportunity seems the greatest. The apparent shortage, therefore, is purely an economic one which reason also accounts for the increased demand for the registered nurse by a public that seems unwilling to engage less well trained nurses

The practice of nursing is no longer an industrial activity. It has become strictly a profession that requires educational qualifications comparable to that of any other profession and which education obviously cannot be held responsible for economic conditions. The law should recognize but one basic type of professional nurse paralleling similar recognition in other professions. Fundamentally nursing is caring for the sick. Caring for the sick at the bedside carries individual responsibility. Therefore, the basic education for bedside nursing should be as advanced and as thorough as for any type of public health nursing or as for any other special nursing activity. The difficulty, if any, resides in the management and conduct of the individual training school and not in the minimum requirements established by law and administered by the Regents. The attitude of the directors of hospital nurse training schools strictly is economic. It would seem that the cost of maintenance of hospital "nurse training schools in New York State has not as yet become as burdensome as the hospital administrators would have the public think. Most hospitals maintaining nurse training schools

still find they can run their hospitals cheaper by using student nurses to do the work of the hospital than in any other way," which "would not seem to indicate that the expense of giving the nurses the very limited instruction which is required had become too burdensome"

As the function of the hospital is to care for the sick, as the student nurse is demanding educational opportunities that hospital administrators assume is placing an unjustifiable financial burden on the hospitals, it would seem that the present system of nurse education is inadequate and soon must undergo radical changes. The hospital nurse training school only should develop experience in caring for the sick at the bedside, applying the principles and practice of nursing taught in extra hospital schools. Under the present minimum requirements of the law such preliminary teaching could be given in the high schools and academies of the State in a vocational course preparatory to entrance to hospital training schools. The qualifying hospital would secure under-graduate resident nurses with theory all finished, whose elementary training would eliminate losses from discontinuance, wastage, housing and maintenance, and, would secure greater efficiency from entrance. In support of the advantages of this high-school-hospital system, Dr Charles R. Mann, Directory of the American

Council on Education at the annual Congress on Medical Education, Medical Licensure, and Hospitals at Chicago February 15-18, 1926, in discussing the defects of medical curricula suggested the use of what is known in industry as "job specifications" for "application to the medical profession so that as far as possible students likely to succeed in medicine could be picked during their elementary and high school course and only those properly fitted for the study of medicine would be permitted to undertake it." The high-school preparatory nurse would automatically eliminate undesirable students whether from mental and physical incapacity or from romantic notions.

I would recommend that the Committee on Economics or a sub-Committee be directed to confer with the Department of Education, the New York State Organizations of Nurses and the New York State Hospital Association to the end that nurse training courses be established in the high schools and academies of the State similar to the courses for household economics, and, whose graduation credentials shall admit such provisional nurses to hospital training schools granting diplomas leading to registered nurse certificates.

A T LYTLE

March 29, 1926

The Reference Committee and the House of Delegates approved the recommendations of the Committee's majority report regarding the establishment and control of Nurses' Agencies by the several County and Medical Societies. They also approved the plan of President Van Etten, (page 459) for a two year basic bedside training for all nurses and state recognition of those who have passed that course.

The minority report was disapproved. Page 459

REPORT OF SPECIAL COMMITTEE APPOINTED TO DRAFT A MEDICAL PRACTICE ACT

To the House of Delegates

GENTLEMEN

Your committee appointed by the President, to prepare a Medical Practice Act, reports as follows

The Committee consisting of Drs Jennings chairman, Chalmers, Stanwix, Leitner, Fisher, Sadlier and Winslow was appointed, and a meeting was held at the Academy of Medicine on June 25th, 1925, at which the President, Dr Van Etten, Drs Jennings, Fisher, Chalmers, Stanwix and Sadlier were present. Plans were discussed, a general program adopted and the meeting adjourned.

Seven subsequent meetings were held at the Columbia University Club on the following dates: July 9th, July 23d, August 6th, August 27th, September 1st, September 22nd and October 22nd. At all of these meetings, with the exception of the first preliminary meeting, legal counsel was present, Mr Oliver of Mr Whiteside's office for the second, third, fourth and seventh meetings, Mr Whiteside for the fifth, sixth and eighth meetings.

Dr Winslow failing to report, Dr Flaherty was appointed in his stead and took his seat at the meeting on August 27th.

Your Committee began its work by a consideration of the present Medical Practice Act and its bearing upon the conditions it is evidently intended to control.

It may be said that public menace from those "holding themselves out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition" in the words of the law, arises from two sources.

The first—those who operate without a license, who have not qualified according to law, the illegal practitioners,

The second—those who having complied with the requirements of the law for admission to practice, abuse the confidence of the public, the profession and of the State.

It is believed that the second group is responsible for as much or more actual evil as the first.

The illegal practitioner of medicine should be detected and brought to justice like any other offender, by the department of justice.

It seems no part of the proper duty of the Department of Education or of medical societies to enforce the law. Hence the proposed act to amend the Medical Practice Act relieves the Department of Education of this burden by providing for one enrollment of all licensed physicians to

complete the rolls and for a mechanism for keeping them thereafter complete.

It is provided that a certificate of endorsement of license shall then be issued to each registrant and that the possession of such certificate shall be recognized as *prima facie* evidence of license, and a failure to produce it on proper demand penalized.

The Attorney General of the State is instructed to assume the enforcement of the Act but it is provided that he shall not interfere in processes already initiated by District Attorneys in counties of over 500,000 population.

The practice without a license is declared *prima facie* evidence of negligence in civil suits arising from damage sustained as a result of such practice.

Misconduct of these admitted to practice—the Profession of Medicine has from time immemorial exacted adherence to a high code of ethics which it is able to maintain among honorable members of the profession. It lacks the mechanism to reach and discipline the men who are beyond the code of honor.

The Board of Regents is now given power to revoke or suspend license to practice, but other measures seem desirable, indeed necessary.

A body analogous to the Grievance Committee of the Bar Association is needed if this important work is to be done.

This Act provided for such a commission on discipline of the physicians to be nominated by the medical societies of the State, to be appointed by the Chief Justice of the Court of Appeals and to function under a method described without pay.

"This commission shall have jurisdiction to hear and determine all charges against duly licensed physicians of this state for violation of the provisions of section one hundred and seventy-four hereof, and shall, upon the finding of such practitioner guilty, have jurisdiction to revoke and annul his license, annul his registration, suspend him from practice or reprimand or otherwise discipline him."

The details of the provisions for the establishment of this body are contained in the Proposed Amendment to the Medical Practice Act which has been prepared by the Committee.

The Council approved the work of the Committee at a meeting held October 29, 1925.

Respectfully submitted,

JOHN E. JENNINGS,
Chairman

March 15, 1926

REPORT OF COMMITTEE ON MEDICAL RESEARCH

To the House of Delegates

GENTLEMEN

The Committee on Medical Research begs to report that up to the present time only one bill on animal experimentation has been introduced in the Legislature. The bill was introduced on March 15th by Assemblyman Alterman to amend the penal law, in relation to experiments upon living dogs.

The bill was referred to the Committee on Codes and no other action has been taken on it up to the present time. The Committee is in readiness at any time to protest against the enactment of this bill, or take any other action that is necessary in order to prevent it becoming a law.

FREDERIC E. SONDERN,
Chairman

March 23, 1926

REPORT OF COUNSEL FOR THE PERIOD FROM APRIL 1, 1925, TO FEB 1, 1926

To the House of Delegates

GENTLEMEN

Counsel herewith submits his report for the period of ten months since the last meeting of the House of Delegates covering the various phases of counsel's activities. During all of this period down to the 15th day of January, 1926, the writer's predecessor, Mr. George W. Whiteside, was counsel for the Medical Society of the State of New York. On that day Mr. Whiteside accepted a most flattering offer to become a member of the celebrated law firm of Chadbourne, Stanchfield & Levy, of No. 120 Broadway, New York City. The opportunity afforded was one which he, of course, could not afford to ignore, although the severance of his relations with the Medical Society which it entailed aroused in him feelings of sincere and deep regret. Mr. Whiteside and the writer, under the name of Whiteside & Stryker, were law partners from June 1, 1912 to January 15, 1926, before which time they were associated together upon the staff of the District Attorney of New York County.

George W. Whiteside was more than a stalwart and effective partner, he was and is a true friend—a friend not only to the writer, but to all the clients whom he served, especially the members of the Medical Society of the State of New York. Without stint he gave all that he had of splendid legal equipment, fine courage, true patience, long experience, sympathetic tact and genuine enthusiasm to the performance of his tasks. By a rare intuition, he seemed to grasp, to comprehend and to master the complicated problems of the medical profession and of its individual members. He spared nothing of time, thought or labor in the upholding of their high standards of professional honor and the espousal of their measures in legislative halls. To the defense of the rights of individual members before courts and juries in practically every county of the state he brought to bear superior skill, experience, effective knowledge and capacity. In the dead of winter in 1923 he traveled to Rochester on a doctor's case. He had a tem-

perature when he started, when he arrived he was taken down with pneumonia. For weeks he lingered between life and death. Through the devoted care of the Rochester General Hospital and the care, vigilance and splendid medical attention of the doctors who attended him there, he was at last restored to health. Thus in defense of the doctors' rights he was willing to and all but forfeited his life.

Since 1920, when Mr. Whiteside became counsel for your Society, the writer of this report, as his partner, conferred and participated with him in the discussion and consideration and solution of medical problems and of malpractice actions. During the first four months of 1923, with Mr. Whiteside suffering with and recovering from pneumonia, the writer took active charge of the problems of the Society and of its individual members, including the defense in court of malpractice actions. Since that time he has tried a number of malpractice actions. In accepting, therefore, the honorable and difficult task of counsel to your Society, the writer approaches the work with knowledge not only of the background, but more important, inspired by the example and ideals of his predecessor—an example which he will have ever before him as an inspiration and a guide.

Perhaps it might not be out of place here to notice how fortunate the doctors have been thus far in avoiding large verdicts. The trend of the times in every other field of negligence law is unquestionably toward larger damages where juries find in favor of the plaintiff. The present value of the dollar is always taken into consideration, so that it is safe to say that where a jury ten years ago might have rendered a verdict for ten thousand dollars, it will now award double that sum or more. Juries have become increasingly liberal with the money of defendants in every other field of negligence cases, when they find against them. Almost limitless examples of this might be presented, for instance, in the United States District Court of Brooklyn a few days ago, a man who lost his leg while employed as a brakeman by the West Maryland Railroad obtained a verdict against the road for \$40,000. At about the same time a girl of four years of age was awarded in Justice Cropsey's part of the Supreme Court in Brooklyn \$25,000 for the loss of her right arm at the shoulder as a result of being run over by a car. There are now in counsel's files a large number of cases where the injuries claimed to have been sustained at doctors' hands are serious, where the bad result alleged is either death, the loss of an arm or a leg or other equally permanent injury. Thus far the doctors against whom suits for such serious injuries have been brought have been fortunate in not sharing the hard fate which so many other defendants in the negligence field have had to face. Malpractice is but one department of the law of negligence. Every time a doctor is called upon to face a charge of this kind in court, his chance of a verdict being rendered against him increases with the tendency of the times. The legal hazard of medical practice does not diminish—it constantly increases.

It will be noted that the number of doctors who have availed themselves of the splendid protection afforded by the Society's group plan

of insurance has increased since the last Annual Report by 388 or by two per cent. Fifty-three per cent of all the doctors eligible for this protection have now availed themselves of the opportunity which your Society has so wisely planned for them. Of the larger counties it will be noted that in New York the number of insured men has increased by 226 or four per cent, in Kings by 74 or four per cent, in Queens by 24 or four per cent, in Bronx by 34 or four per cent, in Westchester by 18 (the percentage remaining the same owing to an increase of 60 members in the Westchester County Society). In the larger counties the only falling off is noted in Erie and Onondaga Counties, where there has been a decrease of five per cent in each of these counties.

The group plan is working well. It is a great

time to time the writer has sat through the nervous hours waiting for the jury's verdict, closeted alone with some doctor who had not availed himself of this insurance protection, he wishes he were at liberty to quote the words of sharp regret expressed by those who were awaiting their fate at the jury's hands, knowing that if the verdict went against them it spelled their financial ruin or heavy embarrassment.

During this period your counsel has prepared for publication in the Society's Journal, articles in the nature of editorial comment. The editorials include the following:

'Should not the profession discourage baseless malpractice suits?'

'Protection against law suits.'

Malpractice suits—protection therefrom."

A trial by jury shall remain inviolate forever."

TABLE III
SCHEDULE OF PREMIUMS FOR INSURANCE

LINES B—Being Limits of Liability For All Claims or Suits During Any One Policy Year	COLUMNS A—Being Limits of Liability for Any One Claim or Suit							
	\$5000	\$10000	\$15000	\$20000	\$25000	\$30000	\$40000	\$50000

benefit and should be a great source of comfort to the profession at large. The insurance carrier is fully alert to the peculiar needs and the special demands of the medical profession and carries on its work with a full understanding and constant recognition that the primary consideration of the doctor at all times is the due consideration and just preservation of his professional honor. The writer, who has traveled during the past three years throughout the state in the defense of malpractice actions, has never heard a word of criticism of this well-conceived group plan. He has, on the contrary, on all sides heard commendation and appreciation of its value and importance to the Society and approval of its method of operation. From none, as might well be imagined, has more enthusiastic comment come than from those who were unfortunate enough to find themselves engaged in vindicating in court their own professional conduct. From

"A series of five articles entitled "The Government of a profession."

"A bill to license chiropractors to practice medicine."

Some of the cases which have been disposed of by counsel in the past have been digested and published in the JOURNAL, among which were the following:

Claimed breach of contract to cure—death—ether anaesthesia at delivery."

Alleged negligence in operation with resultant loss of ovary."

"Alopecia as a result of X-ray therapy."

"Claimed infection from retained placenta."

"Needle breaking in hypodermoclysis."

"Claimed X-ray burn with resultant ulcer and amputation of leg."

"Infected finger."

"Claimed improper administration of chloroform and operation on carbuncle."

"Claimed dislocation of femur by forceps delivery."

"Injured ankle—subsequent infection."

"Contraction of leg due to operation."

"Lumbar puncture—paralysis—death."

"Uterine tumor, X-ray burn."

'Claimed negligent operation resulting in loss of kidney'
 'Breaking of X-ray apparatus'
 "Negligent treatment of rash on face"
 "Burn from hot sand bag in operation"
 "Fracture of the humerus—Volkmann's paralysis"
 "Colles' fracture"
 "Claimed death as result of tonsillectomy"

In addition to the correspondence necessary in the handling of malpractice cases, general correspondence during the period has included the following

Communication regarding fake diploma mill and fake doctor menace in the United States

Communication regarding legality of corporations engaged in X-ray work

Communications on violations of the Harrison Narcotic Law

Communication on the chiropractor practicing medicine
 Various communications on the use of title "Doctor" by chiropodists

Communication re doctors' dispute of fees

Communication re practice of medicine by corporation

Advice as to right of a nurse to attend injured employees at an employer's private hospital

Communication with reference to the recommended alteration of existing laws wherever necessary so that physicians may legally give contraceptive information to their patients in the regular course of practice

Communication with reference to graduated but unlicensed physician practicing medicine

Communication with reference to the practice of the religious tenets of a church.

Communication with reference to insurance coverage on X-ray apparatus for therapeutic treatment.

Communication with reference to the publicity on chiropractors

Communication with reference to the propriety of the use and advertising of bowel evacuant.

Communication with reference to the form of consent to operation.

Advice as to incorporated society rejecting the names of any or all applicants for membership whose names are not recommended by the membership committee.

Advice as to liability and life insurance pre-clinical work and industrial medicine

Communication with reference to the immunity of a person testifying against another

Inquiry as to malpractice actions based upon failure to do a blood coagulation prior to tonsillectomy

Communication with reference to bill to prevent hereditary blindness

Examination of article to be published in Argus

Communication with reference to the use of instruments to produce a miscarriage

Communication with Bronx County Society with reference to amendment of its constitution and by-laws

Communication with reference to the procedure in re the revocation of a license of a physician

Communication with reference to the question of whether a chief of staff in a hospital would be liable for the errors or mistakes made by his assistants

Communication with reference to the statute of limitations in malpractice actions

Communication with reference to the qualifications of a substitute to take the place of a physician on vacation

Communication with reference to the liability of a physician when requested to attend a patient by a third party

Communication with the district attorney with reference to the use of title "doctor" by chiropodists

Communication with reference to the right of a medical society to conduct a clinic.

Communication with reference to the use of the Alpine lamp on patient sent by the family physician to a county sanatorium for ultra violet therapy

Communication on the right of a surgeon practicing oral surgery to extract teeth.

Communication and advice as to whether pamphlet published by chiropractor was libelous of a physician.

Communication with reference to graduated unlicensed physician being left in charge of the office and practice of a licensed physician

Communication with reference to the collection of a physician's bill from an insurance company

Communication with reference to the right of a physician admitted in another state to be admitted to practice in this state.

Communication with reference to the circulation of a list among the members of a society of the patients in the community who have neglected to pay their medical bills

Communication with reference to the liability of a surgeon where sponge has been left in at the time of operation where the nurse has reported all sponges were accounted for

The questions referred to in these communications often require considerable investigation and careful thought and frequently involve the giving of legal opinions and careful analysis and interpretation of legal questions

ATTENDANCE UPON MEETINGS, ETC

Counsel has personally attended or been represented at the last annual meeting of the Society and at each of the meetings of the Council and Executive Committee during the year

Attended a meeting of the Medical Society of the County of Kings and presented a discussion of the present amendments to the Medical Practice Act, likewise attended a meeting of the Medical Society of the County of Queens and made a similar presentation of the features of the Medical Practice Act

The meeting of the First District Branch held at Poughkeepsie was attended by your counsel and an address made to the meeting

Your counsel and his assistant, Mr Oliver, attended the meeting of the Academy of Medicine and both discussed the legal phases of the paper entitled, "The End Results in Tonsillectomy" In the preparation of this paper your counsel assisted the author, Dr Thomas Harris, furnishing him with information for his paper

Your counsel also attended a meeting of the Society of Medical Jurisprudence and there likewise presented the features of the amendments to the Medical Practice Act

LEGISLATIVE MATTERS

In consultation with the Executive Committee and the sub-committee thereof in charge of the revision of the Constitution and By-laws, your counsel had prepared a bill to amend the Charter of the Society to provide for the creation of a Board of Trustees and has also prepared a memorandum in support of this proposed legislative bill

In consultation with the chairman of the Committee on Constitution and By-laws, a revision

of the Society's Constitution and By-laws, providing for the Board of Trustees and a President elect, was prepared by your counsel.

Your counsel or his associate, Mr. Oliver, attended all of the meetings held by the special committee to draft the Medical Practice Act which met during the past summer and fall and aided and assisted the Committee in the preparation of the Society's Medical Practice Act.

In connection with this legislation, your counsel had also attended conferences at Albany with the Legislative Committee and with the representatives of the State Department, has likewise conferred with members of the Board of Regents and has attended and participated in a joint conference of the Committee on Legislation, the special committee to draft the bill, representatives of the State Department of Education and the Board of Regents, which further considered the proposed Medical Practice Act and discussed further amendments thereto.

In connection with the proposed Medical Practice Act your counsel has prepared various drafts of the bill and had the same rewritten a number of times.

Your counsel has also prepared another bill to provide for furnishing the Board of Regents with the lists of physicians dying during the year.

From time to time during the legislative session, your counsel has received from the Society's Legislative Committee bills which have been introduced in the legislature affecting the medical profession and has examined these bills and expressed his views and given opinions upon the legal phases thereof to the chairman of the Legislative Committee.

Nurses—Your counsel has received communications and reports from the Committee inquiring into the nursing situation and has furnished the Committee with opinions with respect to the various phases of the nursing situation as requested by said Committee, has also furnished the executive officer of the Society an opinion as to the interpretation of Section 250 of the Public Health Law relating to the registration of nurses.

County By-laws—Your counsel has received communications from the Medical Society of the County of Bronx for his opinion on various phases of the amendment of the Constitution and By-laws of that Society, and has examined and passed upon the amended Constitution and By-laws of the Bronx County Society, and has likewise been consulted by the Medical Society of the County of Kings with reference to the amendments of its Constitution and By-Laws.

No one can come actively in contact with the medical profession without being impressed by the high standards of professional honor which it

believes in, espouses and upholds. Throughout the period mentioned in this report as during previous years, there has been at all times expressed and displayed a spirit of helpfulness both to counsel and to the unfortunate defendant doctor who was undergoing the strain and worry attendant upon the defense in court of his professional conduct. Large numbers of physicians have been ready when called upon, regardless of personal inconvenience, to aid counsel in the preparation of cases by giving advice on difficult questions of medicine and of medical procedure and by giving their valuable and important expert testimony in court. It is needless to say how deeply valued and how highly appreciated this disinterested scientific assistance has been, not only by the doctors in whose behalf it has been received, but by your counsel on whose shoulders has rested the burden of the doctors' defense. Men of prominent reputation and outstanding ability in their various specialties, without stint or reservation have given of their knowledge, their time and their strength in vindicating unfortunate brother members whose professional honor has been unjustly impugned and assailed. Counsel wishes it were possible by name to mention all those who have thus disinterestedly come forward in this way. Sincerest thanks and appreciation are hereby extended to all those who have rendered this fine, disinterested assistance. They have rendered true service not only to the cause of science, but to the vindication of professional honor and the administration of justice. As your predecessor so well said in his last Annual Report:

"Were the expert testimony of all branches of law to reach the high level of that which is offered in malpractice cases in behalf of the doctors who have been sued, there would be no stigma attached at any time to that type of testimony, but it would receive the great weight which it justly deserves."

Counsel also desires to express to the Council, Executive Committee and officers of the Society his thanks for their hearty and thorough cooperation in the performance of his task during the past year and to acknowledge the valuable aid given in the performance of all the duties of his office by Mr. Robert Oliver, his associate, as well as by the other associates of counsel in his office. Counsel has also received the active and hearty cooperation of Mr. Harry F. Wanvig, who has charge of the administrative details of the group insurance plan in behalf of the Society and of the officers of the Aetna Life Insurance Company, who have cooperated in the handling and disposition of the cases arising under the group insurance plan, to whom he is grateful.

LLOYD PAUL STRYKER, Counsel

The Reference Committee and the House of Delegates commended the work of the Counsel. They also urged the members of the Society to take out indemnity insurance under the plan advocated by the State Society. Page 464

REPORT OF THE COUNCILLOR OF THE SECOND DISTRICT BRANCH

To the House of Delegates

GENTLEMEN

The annual meeting of the Second District Branch was held at the Hempstead Country Club, Hempstead, Long Island, Oct 13, 1925. At this meeting the District Branch combined with the Associated Physicians of Long Island. The two societies cover the same territory geographically, and have an approximately identical membership. In the afternoon many of the members availed themselves of the opportunity for playing golf on the links of the Hempstead Country Club. The business meeting was held at 5 P. M. Dr. D. S. Dougherty, Secretary of the State Society and Dr. Orrin S. Wightman, Editor-in-Chief of the Journal addressed the society at this meeting. After dinner, served in the club house, Dr. Nathan B. Van Etten addressed the assemblage numbering about one hundred. The session closed with an exhibition of the motion picture film, "Motor Functions of the Stomach" and "Gastric Ulcer," prepared under the direction of Dr. Lewis Gregory Cole.

The four counties in the district have been active during the year. The Kings County So-

cety has continued its activities in graduate medical education, including the Friday afternoon lectures and the program prepared by the Joint Committee for Graduate Medical Education of the Long Island Medical College Hospital and the County Society. Queens County has made a beginning along the same line and is now offering Friday afternoon lectures every two weeks. These lectures have had an average attendance of about 60. In addition the society, by the co-operation of the Medical Staffs and Boards of Trustees of the several hospitals in the county has prepared a program of clinical courses at the hospitals. It is as yet too early to state what degree of success this plan is going to attain.

The work of graduate medical education in Nassau and Suffolk Counties also is going forward. Details will probably be given in the report of the Committee on Graduate Medical Education.

Respectfully submitted,

JOSEPH S. THOMAS,
President

March 15, 1926

REPORT OF THE COUNCILLOR OF THE THIRD DISTRICT BRANCH

To the House of Delegates

GENTLEMEN

As President of the Third District Branch of the Medical Society of the State of New York, I respectfully report as follows:

I assumed office after the meeting of the State Society at Syracuse.

A meeting of the Executive Committee was held in June, at which the affairs of the Branch were discussed in detail, and a program was mapped out for the fall meeting. A good attendance was had.

As an innovation, the fall meeting was held at Twilight Inn, Twilight Park, in the Catskills. About 100 members were present, the program was given in full, and was declared by the members present as one of unusual merit. Close attention was given to every paper, and all reported as having a very instructive program, and a fine time in general. A special effort was made to entertain the ladies present.

A meeting of the Executive Committee was held in November, at which Dr. Shaw, Chair-

man of the State Committee on Legislation, presented a rough draft of the Medical Practice Act, as drawn by the Special Committee of the State Society. The proposed bill was thoroughly discussed by Dr. Shaw, Dr. Lawrence and other members of the committee, and it was unanimously voted to support the bill.

Another meeting of the Executive Committee will be held this month in furtherance of medical legislation.

I have visited, or had visited, every Society of the Branch, and report them all in prosperous condition.

I wish to express my thanks for, and appreciation of the aid given me during the year, by my fellow officers.

The territory covered by the Branch is too great—full 75 miles from one end to the other. In my opinion a change could be made by which the meetings could and would be better attended.

Respectfully submitted,

CHARLES P. McCABE, *President*

March 15, 1926

REPORT OF THE COUNCILLOR OF THE FOURTH DISTRICT BRANCH

To the House of Delegates

GENTLEMEN

I have visited but one County Society in my district during the past eight months

So far as my information goes the County Societies are well organized and active

There are counties in this Fourth District that have no County Society, Hamilton, for example

It is not practical to organize one in this County

I know of only one resident M D in Hamilton County who remains during the entire year

Montgomery County has provided for courses in Post Graduate education, the first

meeting in the course began March 12, 1926

The meeting of the Fourth District Branch last year was held in Amsterdam. Something more than 75 were in attendance

Drs Van Etten and Dougherty, President and Secretary of the State Society, were present, and gave interesting and constructive addresses

Dr Joseph Lawrence, Executive Officer, was present and addressed the meeting

The scientific program was well arranged and proved of great interest

Respectfully submitted,

Horace M Hicks,
President

March 15, 1926

REPORT OF THE COUNCILLOR OF THE FIFTH DISTRICT BRANCH

To the House of Delegates

GENTLEMEN

If we could always make our plans work, as we should desire to, we would accomplish a great deal more than we do, but lack of the necessary time, and the means, often curtail our expectations, but if we always reached our desired goal here, possibly we would not want to die some time and go to Heaven. I had hoped to do more for my district during the last two years than I have been able to do, but our district meetings have been very satisfactory, thanks to my very efficient secretary Dr W J McNerney. I wish also to here express my sincere thanks to Dr Hutchings and Dr Cheney, of Utica State Hospital, for their thoroughly good help at our last fall meeting at Marcy, N Y. Although handicapped by a very rainy day, and roads very slippery, and hard to negotiate, we had a very creditable meeting, over 100 being present from the district. It was a pleasure to welcome to our gathering Dr Nathan B Van Etten, of New York City, President of the State Society. We were also pleased to have with us Dr Frank Overton, editor of State JOURNAL, also Dr Joseph S Lawrence our Executive Secretary. Our meeting was held at Marcy, N Y. Marcy is a branch of Utica State Hospital, and thanks to Drs Hutchings and Cheney we were royally entertained in most comfortable and congenial surroundings, a wonderful luncheon and a good time. Dr Richard H Hutchings, Superintendent of Utica State Hospital, gave an address of welcome and said he hoped more of us would be compelled to come to his hospital, but if we were so compelled, he would see that we had good care.

Dr Clarence O Cheney, Superintendent of Marcy branch of Utica State Hospital, gave a remarkable paper on "Treatment of Paresis with Inoculations of Malaria." He also reviewed the work along the same line by other men in other hospitals. He presented a series of cases, which cases showed the very great improvement of the reaction, brought about by the fever of patients after being inoculated. Dr Wright of Syracuse led in discussion of the paper.

Dr I H Levy of Syracuse gave to the meeting a very scientific discourse on the subject of "Diagnosis of Cancer of the Stomach with Reference to Acid Values." Discussion opened by Dr Clark J Laus of Syracuse.

"Surgical Procedures in Acute Perforating Peptic Ulcers," was well covered by Dr Gilbert D Gregor of Watertown. Discussion was opened by Dr Hyzer W Jones of Utica. After luncheon, business session was held and Dr Charles D Post of Syracuse was elected president of branch for next two years. Dr William J McNerney of Syracuse, our worthy Secretary, was re-elected. Election was followed by a very polished and scholarly address by our genial president, Dr Nathan B Van Etten, who always seems to say the right things at the right times.

Our old friend and public health worker, now Executive Editor of The State Journal of Medicine, Dr Frank Overton, who is always a very welcome guest at our meetings, gave us an instructive and pleasing paper on "Medical Publicity."

Dr Joseph S Lawrence, Executive Secretary, gave a well thought out plan on "Some Opportunities of the District Branch."

"Post Graduate Medical Education" was scientifically presented by our very good friend from Syracuse, Dr. Herman C. Wolkotten, member of Committee on Public Health and Medical Education and Commissioner of Health of Syracuse.

Dr. Henry W. Schoenbeck of Syracuse gave us one of the best papers of the day on the subject "Relief Measures During Labor."

Dr. George H. Bonnefond of Utica opened discussion on paper. A very splendid meeting, thanks to all who helped to make it so.

I believe our income as a State Medical Society is about \$100,000 per annum. Now let's remind the trustees to be of the State Medical Society that \$100 a year to supply means to care for District Branches of our society is a joke, but possibly no joke to the presidents of the District Branches when they expend, some of them a few hundred dollars a year, to try and make the Branch do the work it should. One thousand dollars could easily be used to advantage by each Branch in increasing the work which has already been begun.

I have been unable to visit as many county meetings as I had hoped to do, but I have kept tabs on work by doctors in the Fifth District and it has been of a high order and generally efficient.

Orondaga County, with a college town, Syracuse, in the county, has a large and very excellent Society. It also has an Academy of Medicine that is doing good work. Its health activities, asisted as they are by the Milbank Foundation, are of a high order.

Oneida County Society is a large and thoroughly alive organization.

Herkimer County has a very active and worthy society and the men are thoroughly up to date.

Jefferson County has a large society and the men are active. Watertown has a good academy of medicine.

Lewis County has a good society, while not so large as some counties, it has good men.

Oswego County has an active society well manned and working well. Oswego and Fulton all have good and active men.

Madison County has a small society, but it always functions well. Three meetings each year are held in which there is always much interest.

Respectfully submitted,

NILSON O. BROOKS,
President

March 15, 1926

REPORT OF THE COUNCILLOR OF THE SEVENTH DISTRICT BRANCH

To the House of Delegates:

GENTLEMEN:

Since the Annual Meeting at Syracuse the activities of the Seventh District Branch have consisted of one meeting at Auburn on Thursday, September 24th. The program as follows:

"The Treatment of 'Le Doulaureux,'" Ward Williams, M.D., Rochester, N. Y.

"The Treatment of Scarlet Fever," Perry A. Bly, M.D., Municipal Hospital, Rochester, N. Y.

"Correct Control Education in Litch County," John M. Swan, M.D., Rochester, N. Y.

"Certain Aspects of Ureteral Structure," Alfred K. Bates, M.D., Auburn, N. Y.

Discussion opened by Dr. Thomas F. Laurie, Syracuse, N. Y.

"Infections of the Hand," Harry R. Trick, M.D., Buffalo, N. Y.

Discussion opened by Dr. W. W. Skinner, Geneva, N. Y.

"Results Obtained from Long Continued Use of Insulin," John R. Williams, M.D., Rochester, N. Y.

"Bonesetters, Chiropractors, et al," E. T. Wentworth, M.D., Rochester, N. Y.

"Problems of the State Society," by the President and Secretary of the State Society.

The papers were all freely discussed.

The bi-annual election of officers was held and the following are the new officers:

Claude C. Lytle, M.D., Geneva, N. Y., President, G. Kirby Collier, M.D., Rochester, N. Y., 1st Vice-President, Alfred W. Armstrong, M.D., Camandaigua, N. Y., 2d Vice-President, John A. Lichty, M.D., Clifton Springs, N. Y., Secretary, E. T. Wentworth, M.D., Rochester, N. Y., Treasurer.

The Cayuga County Medical Society acted as host and a very delightful luncheon was served. There were about one hundred members present.

The Counties of Wayne, Ontario, Livingston and Monroe were visited by the District President and found to have good attendance. They were keenly alive to the medical problems of the State Society and had excellent scientific programs.

Respectfully submitted,

WILLIAM I. DEAN,
President

March 15, 1926

REPORT OF THE COUNCILLOR OF THE EIGHTH DISTRICT BRANCH

To the House of Delegates

GENTLEMEN

For the past several years the work of the various County Societies has been carried on so directly with the State Society, especially since the inauguration of an Executive Officer, that the work of the Councillor has been limited very largely to attending Council Meetings, Hearings, etc., and the preparation of the program for the Annual Meeting.

The Annual Meeting of the Eighth District Branch has been reported in a previous issue of the JOURNAL.

The component County Societies of this Dis-

trict are alert and active and are co-operating wholeheartedly with the officers of the State Society in their various activities.

At the present time the entire Eighth District Branch is grieving over the loss of our beloved leader, Dr Grover W Wende.

We are stunned by the suddenness and awfulness of this calamity, but his influence is still strong among us and we hope soon to be able to take up our burdens again and to carry on the work as he would want us to do.

Respectfully submitted,

HARRY R. TRICK, *President*

March 15, 1926

REPORT OF THE SPECIAL COMMITTEE TO INCREASE FELLOWSHIP OF THE AMERICAN MEDICAL ASSOCIATION

To the House of Delegates

GENTLEMEN

I am sorry to say that the committee to canvass the State for membership in the American Medical Association has nothing to report. I have had letters from several secretaries of county societies refusing to act in their county as a member of this committee. I believe I was appointed myself without being asked if I could so serve.

Furthermore the state society did not state whether there were funds available for me to engage the necessary clerical assistance. I have been so busy myself that the year has passed before I realized that the annual meeting of the State society was about here.

Respectfully submitted,

Harrison Betts, *Chairman*

March 15, 1926

HOUSE OF DELEGATES

The Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Hotel Waldorf-Astoria, New York City, N Y, Monday afternoon, March 29, 1926, at two o'clock. Speaker, Dr E. Eliot Harris, presiding, Dr Daniel S Dougherty, secretary. The Speaker announced that the secretary would call the roll by counties, for the purpose of determining the presence of recognized delegates. A quorum being present, the House was declared by the Speaker organized for business.

REPORT OF COMMITTEE ON CREDENTIALS

The Speaker The first order of business is the report of the Committee on Credentials, Dr Dougherty.

Dr Dougherty Mr Speaker and gentlemen, the Committee on Credentials have the pleasure of reporting that there is no duty for them to perform, as there are no disputed delegations. In looking over the list of the House delegates I find that some of the delegates are also officers of the Society. I would like to have a ruling as to the voting of those gentlemen, whether they can vote as officers and as delegates, or whether they must determine in which capacity they shall vote.

The Speaker In this House each member of the House is an individual and as an individual he has one vote.

Dr Rooney, Albany In view of the ruling of the Chair that each member of the House as an individual has a right to vote, I would like to ask whether that in the opinion of the Speaker relates to past presidents of the Society who in accordance with the constitutional provision have been members of this House but without vote.

The Speaker It is provided in the constitution that they are members of the House with voice but without vote, and there is no ruling or action of this house that can overrule the constitution and by-laws.

Dr Podzun, Bronx In Bronx County we have one of our regularly elected delegates who is a member of a Standing Committee. I understand that as chairman of the Standing Committee he is a member of this House, is that correct?

The Speaker That is correct.

Dr Podzun Would it be within our power to substitute an alternate in his place as delegate?

The Speaker That is repeatedly done where the elected delegate does not wish to register as a delegate. His alternate may take his place.

Dr Podzun He will have a vote in the House.

The Speaker Yes, after he passes the Committee on Credentials.

IN MEMORIAM OF DRs SUITER AND WENDE

The Speaker It is my sad duty to call the attention of this house to the death of two members since we last met—Dr A. Walter Suiter and Dr Grover W. Wendé, ex-presidents of this Society. I shall ask the House to rise and remain standing for two minutes in silence out of respect to the memories of Dr A. Walter Suiter and Dr Grover W. Wendé, former presidents of this Society. The House will please rise.

The House thereupon rose and remained standing in silence for two minutes in respect to the memories of Dr A. Walter Suiter and Dr Grover W. Wendé, deceased.

APPROVAL OF MINUTES

The Speaker The minutes of the previous meeting have been published. Are there any corrections or additions? Hearing none, they will stand approved as printed and it is so ordered.

PRESIDENT'S ADDRESS.

Next is the address of the President, Dr Van Etten. *President Van Etten* I have no desire to add materially to the president's address as printed in the report (see p) I would simply feel that it were discourteous perhaps to you not to reiterate my thanks and appreciation of the honor which you have conferred in electing me to the presidency of the greatest Medical Society in the world. I entered upon this office with a sense of a good deal of responsibility and with a great deal of apprehension. I found that while there was a great deal of responsibility, there was not much apprehension because everybody in the Society seemed determined to give me a very good time. I have had a perfectly delightful year. I have met more members than I ever met in my life before. I have had a remarkable spirit of cooperation and reciprocity. I have been delightfully entertained all over the state. One of the best times I had was given to me by a doctor who cooked the dinner himself, served it himself, in one of the most delightful atmospheres that one could possibly wish.

This administration has been a very busy one, as it naturally would be with the increased opportunities that have been offered. If the administration has failed in any wise, it has been due entirely to defects of the head and not of the heart. If the administration has succeeded, the success of this administration is due to the remarkable cooperation of the committee chairmen, of the committeemen, and of all the other officers of the Society. To the Executive Committee I wish to pay especial tribute. I think no man ever had a better Executive Committee than I have had. The members of this committee have attended every meeting that they were physically able to attend and have given close, undivided, concentrated attention to the problems of the Society. If there has been any success in the past year, it has been due to the work of the committee heads, the Council and the Executive Committee, and to the cooperation of you all. I thank you.

SPEAKER'S ADDRESS

The Speaker The next is the address of the Speaker. As that has been printed, I shall ask consent that it be referred without being read.

Upon motion duly made, seconded and carried, the address of the Speaker was referred to the proper Reference Committee, as was also the address of the President.

REFERENCE COMMITTEES

Dr Dougherty I move that every other report be sent to the proper Reference Committee as printed, without reading them before this House of Delegates. Seconded and carried.

The Speaker Mr Secretary, please read the Reference Committees as appointed by the speaker.

The Secretary Dr Dougherty Reference Committee on Speaker's Address—Constitution and By-Laws—Andrew Sloan, Oneida Chairman, J. Richard Kevins, Kings, Harry Aranow, Bronx, Floyd S. Winslow, Monroe, William B. Hanbridge, St. Lawrence.

Reference Committee on President's Address—Frederic E. Sondern, New York, Chairman, Charles R. Borzilleri, Erie, W. Francis Campbell, Kings, Thomas C. Chalmers, Queens, Edward W. Weber, Westchester.

Reference Committee on Reports of Secretary and Treasurer—Henry C. Courten, Queens, Chairman, James N. Vander Veer, Albany, George W. Cotus, Chautauqua, George R. Critchlow, Erie, George A. Leitner, Rockland.

Reference Committee on Report of Committee on Legislation—John E. Jennings Kings, Chairman, Henry S. Patterson, New York, Addison H. Bissell, Otsego, Herbert B. Smith, Steuben, Luther C. Payne, Sullivan.

Reference Committee on Reports of Committee on Public Health and Medical Education—Edward C. Podvin, Bronx, Chairman, Robert H. Halsey, New York, Luther Emerick, Ulster, John Douglas, New York.

Reference Committee on Report of Committee on Scientific Work—O. Paul Humpstone, Kings, Chairman, Cornelius J. Egan, Bronx, Reeve B. Howland, Chemung, Henry G. Hughes, Schenectady, Luzerne Coville, Tompkins.

Reference Committee on Reports of Council and Councillors—William P. Healy, Chairman, New York, George A. Newton, Nassau, Arthur G. Bennett, Erie, J. Lewis Amster, Bronx, George Mord, Richmond.

Reference Committee on Report of Legal Counsel—Terry M. Townsend, New York, Chairman, Thomas W. Jenkins, Albany, John L. Edwards, Columbia, Homer J. Knickerbocker, Ontario, George M. Cady, Tioga.

Reference Committee on Report of Committee on Medical Economics—Charles E. Scofield, Kings, Chairman, Arthur J. Bedell, Albany, Frederick J. Schnell, Niagara, Edward B. Jones, Onondaga, Ernest E. Smith, Queens.

Reference Committee on Report of Special Committee on Nurses—Samuel J. Kopetzky, New York, Chairman, Chauncey R. Bowen, Allegany, George D. Johnson, Chautauque, William A. Jewett, Kings, W. Grant Cooper, St. Lawrence.

Reference Committee on New Business—A—Frank M. Dyer, Broome, Chairman, William M. Dunning, Bronx, John E. Safford, Delaware, Joseph B. Hulett, Orange, Peter L. Harvie, Rensselaer.

Reference Committee on New Business—B—Walter D. Ludlum, Kings, Chairman, Lyle B. Honeyford, Greene, Warren Wooden, Monroe, William R. Thomson, Wyoming, William H. Cantle, Westchester.

Reference Committee on New Business—C—DeWitt Stetten, New York, Chairman, Raymond C. Almy, Cayuga, Earl P. Lothrop, Erie, John R. MacElroy, Saratoga, John A. Hatch, Yates.

Reference Committee on Credentials—Daniel S. Dougherty, New York, Chairman, John P. J. Cummins, Essex, Sidney F. Blanchet, Franklin, Arthur W. Albones, Herkimer, J. Leonard Byrnes, Washington.

The Speaker The next is unfinished business.
Dr. Kopetzky In regard to the references in the President's address there is a reference to the nursing situation, which has a direct bearing upon the report of the Special Committee on Nursing. May I ask you sir whether it would be appropriate to refer that portion of the President's address to the same reference committee that is dealing with the subject of nursing so that the Reference Committee might have the topic from both angles before it?

The Speaker The Speaker will order that that portion of the report of the President which relates to nurses be referred to the Committee on Nursing.

ENDORSEMENT OF MEDICAL PRACTICE ACTS, AND LEGALITY OF ACT OF THE COUNCIL

Now we are under the heading of new business.
Dr. Brennan Kings At the regular meeting of the Medical Society of the County of Kings held March 16th, 1926 the following resolutions were adopted:

The delegates from the Medical Society of the County of Kings to the House of Delegates of the Medical Society of the State of New York are directed to present and urge the adoption of the following resolutions:

"RESOLVED That no medical measure affecting the welfare of the medical profession of New York State be proposed or sent to the State Legislature unless a referendum vote be taken by the separate county medical societies and approved by a majority of them.

RESOLVED The State Legislative Committee shall not endorse or approve in the name of the Medical Society

of the State of New York any medical practice act or amendment thereto, without referendum to the component County Medical Societies following notification to every member of the State Society by prompt publication of proposed legislation in the "New York State Journal of Medicine" or a bulletin thereof.

That the attention of the House of Delegates of the Medical Society of the State of New York be hereby directed to the failure on the part of the Council to act in accordance with a direct order of the House of Delegates at the last session with reference to the Medical Practice Act.

Referred to Reference Committee on New Business—B (Report on page 461)

MALPRACTICE DEFENSE

Dr. Ross, Suffolk I desire to offer the following resolution:

WHEREAS, There was adopted by the House of Delegates at their annual meeting, May 11, 1925, the following resolutions:

1. Members shall be entitled to malpractice defense of any suit arising from any one claim in each calendar year, of alleged malpractice error or mistake done in the performance of his profession as a physician.

2. The Society shall not at its own expense appeal from any judgment that may be entered against a member in any malpractice suit.

3. The Society shall not be obligated to defend any malpractice claim or suit against any member when such claim or suit is covered by any policy of insurance carried by such member.

But nothing herein contained shall be deemed to curtail, abrogate, or restrict, the rights of any member under the group insurance plan endorsed by the Society.

THEREFORE BE IT RESOLVED, That said resolutions be and hereby are rescinded."

TIME OF MAKING ANNUAL REPORTS

I also offer the following resolution:
"RESOLVED That the Council shall have the power to decide whether or not a member is entitled to legal defense by the State Society against alleged malpractice claim or suit, and how many times, and to what extent he shall be defended for any claim or suit, and what aid shall be rendered in case of appeal from judgment of the court, and the procedure for conducting the defense shall be that authorized by the House of Delegates April, 1914 and such other rules and regulations as the Council may authorize." Page 460.

Dr. Ross I also offer the following resolution:
"RESOLVED That the annual reports of all officers and committees, to the House of Delegates, shall be submitted to the Council one month in advance of the annual meeting of the House of Delegates, to be published in the Journal before the annual meeting, and the Chairman of the Executive Committee shall supplement at the annual meeting of the House of Delegates his written report with a verbal or written report of the activity for the last month."

Referred to Reference Committee—B (Report on page 461)

CONTRIBUTIONS FOR CANCER CONTROL

Dr. Henry Monroe I offer the following resolution:
"WHEREAS, in an attempt to prevent the further increase of deaths from malignant tumors, the New York State Committee of the American Society for the Control of Cancer has inaugurated a three year educational program in the State of New York.

AND WHEREAS The New York State Committee of the American Society for the Control of Cancer expects to finance this program by asking for voluntary contributions from each County in the State on a basis of \$7.25 per thousand population.

THEREFORE BE IT RESOLVED by the House of Delegates of the Medical Society of the State of New York that

they approve of this program and that they recommend that all physicians support it and recommend its support to the people in their communities."

Referred to Reference Committee on New Business
—A (Report on page 460)

DISTRICT BRANCHES, REARRANGEMENT OF

Dr MacFarlane, Albany Presented the following plan for the re-districting of the District Branches

First District to include the Counties of Bronx, Dutchess, New York, Orange, Putnam, Rockland, Sullivan, Ulster, Westchester

Second District to include the Counties of Kings, Nassau, Queens, Richmond, Suffolk

Third District to include the Counties of Albany, Columbia, Greene, Montgomery, Rensselaer, Schenectady, Schoharie

Fourth District to include the Counties of Clinton, Essex, Franklin, Fulton, Hamilton, Saratoga, Warren, Washington

Fifth District to include the Counties of Herkimer, Jefferson, Lewis, Madison, Onondaga, Oneida, Oswego, St Lawrence

Sixth District to include the Counties of Broome, Chenung, Chenango, Cortland, Delaware, Otsego, Tioga, Tompkins

Seventh District to include the Counties of Cayuga, Livingston, Monroe, Ontario, Schuyler, Seneca, Steuben, Wayne, Yates

Eighth District to include the Counties of Allegany, Cattaraugus, Chautauqua, Erie, Genesee, Niagara, Orleans, Wyoming

The Speaker As that is an amendment to the Constitution and By-Laws, it will be placed on file with the Secretary

SARATOGA SPRINGS, STATE MINERAL WATER RESERVATION

Dr MacElroy, Saratoga I beg to offer the following
"WHEREAS The Medical Society of the County of Saratoga has adopted the following resolution

"WHEREAS The Conservation Commission of the State of New York has announced comprehensive plans for the development of the State Mineral Water Reservation at Saratoga Springs including many provisions for the therapeutic uses of the waters, and

"WHEREAS The therapeutic applications of the mineral waters constitute a medical problem whose solution and application belong to local physicians, therefore, be it

"RESOLVED That the Medical Society of the County of Saratoga accepts the responsibility that falls upon it as the group of physicians nearest the proposed development of a public utility having an important medical phase, and be it further

"RESOLVED That the Society approves the plans of the Conservation Commission

"THEREFORE BE IT RESOLVED That the House of Delegates of the Medical Society of the State of New York in stated session approves the principles of the action embodied in the resolution"

Referred to Reference Committee on New Business
—A Report on page 460

REFERENDUM IN LEGISLATIVE MATTERS

Dr Dyer, Broome The constitution provides that when the House of Delegates is not in session the duties of the House of Delegates may be exercised by the Council and the by-laws provide that all committees shall report and be subject to the Council, also that the Council—and here is a cause of misunderstanding on the part of some of the individuals—in section twenty-four provides that the Council in any legislative action shall take a referendum vote To clear up that feature and to make sure that no committees shall inaugurate direct legislative action themselves without reporting to the Council and the Council shall take a referendum vote, the County of Broome offered an

amendment to the present section 54 of the by-laws which shall read, after the present last line, in regard to the Committee on Legislation "It shall not present to the Legislature of New York State or sponsor legislation affecting medical practice until approved by the House of Delegates"

The Speaker As that is a proposed amendment to the By-Laws, it will be placed on file with the Secretary
Dr Eastman, Ulster In line with the foregoing resolution Ulster County voted to submit the following resolution to the House of Delegates

"RESOLVED, That no Medical measure affecting the welfare of the medical profession of New York State be proposed or sent to the State Legislature unless a referendum vote be taken by the separate county medical societies and approved by a majority of them."

Referred to Reference Committee on New Business
—C Page 461

FUNCTION OF VISION, DEFINITION OF

Dr Bedell, Albany "RESOLVED, That the House of Delegates of the Medical Society of the State of New York re-affirms its approval of its former resolution that it considers the function of vision to be a compound act consisting of three factors central visual acuity, field of vision, and muscle function"

Referred to Reference Committee on New Business
—B (Report on page 461)

The Speaker Any further new business?

Dr Lytle, member of the Committee on Nurses, would like to present his views Before they can be received, he must have the consent of the House, I will put the question All those in favor of receiving the minority report presented by Dr Lytle will please say aye, opposed, no Carried

Dr Lytle read the minority report of the Committee on Nursing (See pages 442 and 459)

Referred to Reference Committee on Nursing

REPORT OF SPECIAL COMMITTEE ON WORKMEN'S COMPENSATION

Dr Critchlow, Erie As a matter of information I would like to ask what is to be done with the report of the Special Committee appointed by the President on Compensation Law This report, I understand, was not ready in time to be published with the other report but the report is in the hands of the Secretary I simply wanted to ask for information, whether that comes up now as a matter for reference.

The Speaker That report was referred to the Committee on Legislation

Dr Rooney, Albany It occurred to me if the report has not been published that perhaps the House might wish to hear at least the conclusions of the report, not of necessity the argument but the conclusion of the report, and I would, therefore move you sir, that the conclusions of this report be read so that they might be presented to the House. Seconded

The Speaker It is moved and seconded that the report on the Workmen's Compensation be read, or the conclusions of it, for the enlightenment of the House. All in favor of that motion say aye. All of those opposed no Carried

The report was read (see page 432)

Report was referred to the Reference Committee on Legislation Page 465

COUNSEL'S ADDRESS

The Speaker Members of the House of Delegates, since we last met Mr Whiteside has made other business connections and his partner Mr Stryker, has assumed the duties of Counsel to the State Society in order that we might become acquainted with him, I am going to ask Mr Stryker to address you

Mr Stryker Mr Speaker and members of the House of Delegates I appreciate very keenly the honor that the speaker has conferred upon me in permitting me to

introduce myself to you. My partner, George Whiteside is known to every man in this room. He has left you but his spirit and his interest in you have not gone, and the ideals and the standards that George Whiteside had in maintaining the high standards of the medical profession are those towards which I shall aim.

I see here in this room many old friends from other countries in the state, men that I have met under other circumstances sometimes more hectic even than these.

Gentlemen, I will not detain you except to say that in the two months since I have acted as counsel for the Society I have been impressed anew by the public spirit and the zeal and the interest which the members of your Council and Executive Committee, your officers and your individual members have shown in the Society's welfare. I have had occasion to battle with them and for them in the halls of the legislature on more than one occasion already, and we trust that good results will come from that.

It is a great pleasure to be here before you, gentlemen, and I bring to you George Whiteside's message of good will, regard and good wishes. I thank you for this opportunity to say "How do you do?"

The Speaker If there is no further new business I will entertain a motion for a recess. On motion, seconded and carried, a recess was taken for thirty minutes.

REFERENCE COMMITTEE ON NURSING

The Speaker Is the Reference Committee on Nursing ready?

Dr Kopetsky, New York The Reference Committee on Nurses has had under consideration that portion of the President's address referring to nurses the report of the Committee on Nurses and the minority report handed in by Dr Lytle of the Committee on Nurses, and after studying all angles of the questions presented, recommends as follows:

First The establishment of an official Nurses' Registry in every county of the state on the model of the one already established and functioning in Buffalo.

Second The Committee approves and would have the State Journal carry the approval of all commercial registries who send out nurses for bedside work with a card stating the type of nurse presenting the card whether this individual be a registered nurse, an under graduate nurse a trained attendant, etc., and that the County Societies through appropriate committees get in touch with commercial registries to induce them to seek approval from the State Society of its delegated officer or committee in carrying out the above provision.

Third The Committee heartily approves the recommendation of the President of the Society that there shall be a basicaly trained nurse, specifically trained for bedside work and that this training does not necessarily qualify such a nurse for executive positions of public health work without subsequent further study on her part. In line with this idea your Committee approves the recommendation of the Committee on Nursing that the President appoint a committee to confer with similar committees from the State Hospital Association and the State Educational Department to formulate a basic course of study for the bedside nurse stressing the practical sides of nursing and reducing to the minimum the purely theoretical training, that this nurse shall be known under the general title of trained nurse, and that the conferences of these committees should be so directed that certain hospitals having a specific problem to meet in the community who will graduate nurses in this group shall be approved by the State Department of Education and thus supply the needed want in the community of bedside nurses.

The above course shall be so arranged that any nurse graduating under its curriculum and later desiring the higher degree of R. N. shall be able to continue her

studies in a school approved by the Regents for giving the supplementary course so that she may eventually be enabled to take the examinations to qualify for R. N.

Your Committee disapproves the Minority Report presented by Dr Lytle as it is impracticable and we doubt the advisability of influencing the curriculums in the high school. Your committee realizes that if we can modify the curriculum in the hospital training schools at the present time, we will have accomplished all that we can hope to without going into the high schools to put into effect a pre-nursing high school curriculum. Page 458.

Fourth In conclusion your Committee feels that while investigations have been made by the Committee on Nursing of many aspects of the Nursing Problem, the one salient aspect of the question has not been studied, and we recommend that the Nursing Committee be continued for another year and that during that year the committee by means within its power endeavor to compile the information as to exactly what the physician demands the needs of the nurses that he uses. Such information would be of great importance to both the nursing profession and the educational department of the Regents in the modification and the formulation of standards for nurses.

The Speaker Will the Chairman of the Committee please read his recommendation by sections?

Dr Kopetsky The establishment of an official Nurses' Registry in every county of the state on the model of the one already established and functioning at Buffalo. I move its adoption.

The Speaker All those in favor of the question say aye opposed, no. Carried.

The next section?

Dr Kopetsky The Committee approves and would have the State Journal carry the approval of all commercial registries who send out nurses for bedside work with a card stating the type of nurse presenting the card whether this individual be a registered nurse an under graduate nurse a trained attendant, etc., and suggests that the County Societies through appropriate committees get in touch with commercial registries to induce them to seek approval from the State Society or its delegated officer or committee in carrying out the above provision.

The trouble is they call up a registry at the present time and ask for a nurse, and they send out a registry nurse. They may send you an under-graduate, particularly in the large cities, and they charge the same for all of them. If the County Societies would pass a resolution appointing a committee to supervise this thing, get in touch with these registries, and make the nurse present a card, make the nurse who comes on the case present a card so that the doctor can look at the card and see what kind of nurse is coming, she could be paid accordingly. The registry carrying the approval of the State Society is the commercial inducement by which we hope, by moral suasion, to get the commercial registries in line. Where both the doctor and the commercial registries cooperate to defeat the purposes of the State Society in this matter, nothing can be done. It is a matter for moral suasion.

I move the adoption of that recommendation.

The Speaker As there has been a bill introduced in the legislature in regard to the licensing of nurses registries, I will ask Mr Oliver to inform the House as to its enacting clause.

Mr Oliver That bill was an amendment to the general business law with reference to employment agencies, providing that all nurses' registries shall be licensed under the licensing authorities of the particular cities as already provided in the law, and further providing that the nurses sent out from the respective registries shall carry with them, and there shall be forwarded within twenty-four hours to the patient or the person calling for a nurse a card which will state the qualifications of the nurse, including whether or not she

is a graduate nurse or trained nurse, and if not a graduate nurse, where her training has been received from what hospital and for what length of time, and the cost of her services. I think in substance that is what was included in that bill.

The Speaker All those in favor of the adoption of the recommendation on nurses' registries say aye, opposed, no. Carried.

Dr Kopetzky Third, That the Committee heartily approves the recommendation of the President of the Society that there shall be a basically trained nurse specifically trained for bedside work and that this training does not necessarily qualify such a nurse for executive positions of public health work without subsequent further study on her part, and that in line with this idea your Committee approves the recommendation of the Committee on Nursing that the President appoint a committee to confer with similar committees from the State Hospital Association and the State Educational Department to formulate a basic course of study for the bedside nurse stressing the practical sides of nursing and reducing to the minimum the purely theoretical training. That this nurse shall be known under the general title of trained nurse and that the conferences of these committees should be so directed that certain hospitals having a specific problem to meet in the community who will graduate nurses in this group shall be approved by the State Department of Education and thus supply the needed want in the community of bedside nurses.

The above course shall be so arranged that any nurse graduating under its curriculum and later desiring the higher degree of R. N., shall be able to continue her studies in a school approved by the Regents for giving the supplementary course so that she may eventually be enabled to take the examinations to qualify for R. N.

In making the motion to approve the adoption of this recommendation, I again say that the details are left to the committee. We are simply enunciating a general principle and asking the appointment of such a committee. Seconded.

Dr Booth, Chemung I would ask the chairman of the Reporting Committee if he could not also include the State's Nurses' Association. Their advice will be very valuable to any such conference.

The Speaker Will you make that as an amendment?

Dr Kopetzky New York I am willing to accept the amendment.

Dr Ludlum, Kings It is not the State Hospital Association, but the Hospital Association of the State of New York, in contra-distinction to the State Hospital Association.

The Speaker That title will be changed as newer knowledge indicates. Is there any further discussion?

Dr Kopetzky I move the adoption of the recommendation as amended.

Dr Rooney, Albany The New York State Association of Nurses is the one that is by law represented on the Board for Nurses Registration.

The Speaker Is there any further discussion? All those in favor of the recommendation as amended, say aye, opposed, no. Carried.

Dr Kopetzky, New York Fourth, In conclusion your Committee feels that while investigations have been made by the committee on Nursing of many aspects of the Nursing problem, the one salient aspect of the question has not been studied and we recommend that the Nursing Committee be continued for another year and that during that year the Committee by means within its power endeavor to compile the information as to exactly what the physician demands and needs of the nurses that he uses. Such information would be of great importance to both the nursing profession and the educational department of the Regents in the modification and the formulation of standards for nurses. I move the adoption of that. Seconded. Carried.

Dr Kopetzky, New York I move the adoption of

the report of the Reference Committee on nurses as a whole as intended. Seconded. Carried.

CANCER CONTROL.

The next Committee on Reference—A.

Dr Dyer, Chairman of Reference Committee A In regard to the resolution bearing on the program of the New York State Committee of the American Society for control of cancer, the Committee recommends that the House of Delegates approve of their program. I move its adoption. Seconded and carried. Page 457.

Dr Dyer In regard to the program of the Conservation Commission of the State of New York in connection with the mineral springs at Saratoga Springs, the Committee move the adoption of the resolution that the House of Delegates approve that program. Seconded and carried. (See page 458.)

MALPRACTICE DEFENSE.

Dr Ludlum, Chairman, Reference Committee B I think Dr Ross's three resolutions had better be read.

"WHEREAS, There was adopted by the House of Delegates at their annual meeting, May 11, 1925, the following resolutions

"1 Members shall be entitled to malpractice defense of any suit arising from any one claim in each calendar year, of alleged malpractice error or mistake done in the performance of his profession as a physician.

"2 The Society shall not at its own expense appeal from any judgment that may be entered against a member in any malpractice suit.

"3 The Society shall not be obligated to defend any malpractice claim or suit against any member when such claim or suit is covered by any policy of insurance carried by such member.

"But nothing herein contained shall be deemed to curtail, abrogate, or restrict, the rights of any member under the group insurance plan endorsed by the Society.

"THEREFORE, BE IT RESOLVED, That said resolutions be and hereby are rescinded." (See page 457.)

We approve the resolution as offered and recommend its adoption—that is the resolution being to rescind the previous resolutions. Seconded and carried.

The Speaker Next?

Dr Ludlum "RESOLVED, That the Council shall have the power to decide whether or not a member is entitled to legal defense by the State Society against alleged malpractice claim or suit, and how many times, and to what extent he shall be defended for any claim or suit, and what aid shall be rendered in case of appeal from judgment of the court, and the procedure for conducting the defense shall be that authorized by the House of Delegates, April, 1914, and such other rules and regulations as the Council may authorize."

This is an affirmative resolution taking practically the same action as the rescinding of the other, and carrying it further. The Reference Committee approved and I move the adoption of the Resolution.

The Speaker The By-Laws provide that the Executive Committee shall act as advisor to the legal counsel. A correction has to be made to agree with the By-Laws under section thirty.

Dr Rooney, Albany I think the House might be interested in knowing just exactly what the resolutions of 1914 say. If we are practically going back to the provisions as made in that resolution, it seems to me we cannot vote intelligently without knowing what is in that resolution. I would, therefore, request that the resolution that covers this most essential matter of malpractice be read in order that we may know what we are going to do.

Dr Ross Mr Speaker, do you desire the resolution adopted April 27 1914, read?

The Speaker Yes.

Dr Ross The resolutions adopted by the Council at its meeting December 5th 1913 and adopted by the House of Delegates April 27th 1914.

First Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed prior to their admission to membership in the State Society

Second Members who have been dropped for non-payment of dues, if reinstated shall not be entitled to malpractice defense for acts committed during the time they were not members of the Society

Third Active members of the Society desiring to avail themselves of the privileges of this act shall make application therefor in writing to the Secretary of the Society, and it shall be shown to his satisfaction that they are members in good standing in the State Society. They shall also furnish the Secretary a complete and accurate statement of their connection with, and treatment of, persons upon which complaints against them are based giving dates of attendance, names and residences of nurses and of other persons cognizant of facts and circumstances necessary to a clear and definite understanding of all matters in question and shall furnish such other relevant information and execute such papers as may be required of them by the Secretary or the Attorney of the State Society

Fourth A member shall agree not to compromise any claim against him, nor to make settlement in any manner without the advice or consent of the Society given through its Attorney

Fifth In the event that a member sued or threatened with suit shall, without the advice or consent of the Attorney of the Society determine to settle or compromise any claim against him, he shall reimburse the Society for the expenses incurred in undertaking his defense, and in default thereof, he shall be deprived of further privileges under this resolution

Sixth The Society shall not assume any responsibility for the payment of any sum agreed upon by arbitration in the settlement of claims or awarded by court verdicts or for making payments for any purpose whatsoever

Dr Rooney Albany I move an amendment of this resolution in order to bring it into conformity with the present by-laws, where it specifies the secretary and the Counsel of the Society by adding the words "The Executive Committee," so that it will read "The Secretary, the Executive Committee and the Counsel" I move, Mr Speaker, that the old resolution which has been submitted to this House for approval by the Chairman of this Reference Committee be amended so that in the third paragraph there shall be added the words following "The Secretary" these words "the Executive Committee and the Counsel of the State Society"

The Speaker The legal counsel?

Dr Rooney Yes

Dr Ross Now, the actual resolution of the committee has been amended in accordance with the direction of the Chair so that it reads "The Executive Committee of the Council shall have the power" etc "to decide," and in the last sentence also it has "the executive committee may authorize" I was in process of reading in as I understand it that the old resolution of April 27, 1914, shall be so amended that following the words "the secretary" "the executive committee and legal counsel" shall appear

Seconded

The Speaker Are you ready for the question? All those in favor of the amendment of Dr Rooney say aye, opposed no

Carried

All those in favor of the recommendation of the Committee as amended say aye, opposed, no

Carried

TIME OF MAKING ANNUAL REPORTS

Dr Ludlum A further resolution by Dr Ross—That the annual reports of all officers and committees of the House of Delegates shall be submitted to the Council one month in advance of the meeting of the House of Delegates to be published in the Journal before the annual meeting and the council shall supplement at the annual meeting of the House of Delegates its written

report with a verbal or written report of the activities during the last month (See page 457)

The Speaker All those in favor of the recommendation say aye, opposed, no

Carried

FUNCTION OF VISION DEFINITION OF

Dr Ludlum Dr Bedell's resolution is as follows

RESOLVED, That the House of Delegates of the Medical Society of the State of New York re-affirms its approval of its former resolution that it considers the function of vision to be a compound act consisting of three factors central visual acuity, field of vision, and mu cle function" (See page 458)

We recommend its adoption

The Speaker All those in favor say aye, opposed, no

Carried

ENDORSEING MEDICAL PRACTICE ACTS

The Speaker Reference Committee on New Business C.

Dr Stetten Your Reference Committee on New Business C approves of the following resolution of the Medical Society of the County of Ulster and recommends its adoption

RESOLVED, That no medical measure affecting the welfare of the medical profession of New York State be proposed or sent to the State Legislature unless a referendum vote be taken by the separate county medical societies and approved by a majority of them"

The committee also approves the following resolution of the Medical Society of the County of Kings and recommends its adoption

RESOLVED, That the State Legislative Committee shall not endorse or approve in the name of the Medical Society of the State of New York any Medical Practice Act or amendments thereto without referendum to the component county medical societies following notifications to every member of the State Society by prompt publication of proposed legislation in the New York State Journal of Medicine or a bulletin thereof" I move its adoption, seconded

Dr Frank Jennings Kings I offer the following amendment "that said Legislation when approved to be subject to such changes or amendments during its progress through the Legislature as do not essentially change its provisions and which are approved by the Council and the Legislative Committee of the Medical Society of the State of New York."

I move its adoption

Seconded

Dr Rooney Albany In order to clarify this whole matter I move that the whole question be re-referred to the Committee, and that the committee report at the earliest opportunity, after which discussion of the amendment may be had before the house. Seconded and carried

The Speaker It is recommitted to the Reference Committee (See pages 458 and 466)

CENSURE OF THE COUNCIL

Dr Stetten Chairman Reference Committee on New Business C New York Your Reference Committee on New Business C disapproved of the resolution introduced by the Medical Society of the County of Kings regarding failure on the part of the Council to act in accordance with the direct order of the House of Delegates in reference to the Medical Practice Act

Your committee disapproves of this resolution for the following reasons

Although the Resolution offered by Dr Chalmers at Syracuse in 1925 providing for the appointment of a Committee of Seven to draft a Medical Practice Act which shall be the official bill of the Society was carried by the House of Delegates, according to Section 26 of the By-Laws of the Society which reads "The standing or special committees of the Society shall report to the Council and shall be subject to the jurisdiction of the Council at all times when the House of Delegates shall

not be in session," the Council were entirely within their constitutional rights in amending the Act, as submitted to them by the Committee, in order to make it acceptable to the Department of Education.

Your Committee therefore recommends the rejection of this resolution. Seconded

Dr Frank Jennings, Kings My recollection of the verbiage of that resolution is this that the product of that special committee to be appointed by the President shall be the bill of the Medical Society of the State of New York. Now, if the ordinary English means anything, "shall" is mandatory, and that only has arisen in the minds of some of us—as to how when a resolution of the House of Delegates is made mandatory and it is said that the bill or the product of a special committee shall be the bill of the Medical Society of the State of New York—how then can some other bill come along which is not the product of that committee. I think that is a question at issue, sir

The Speaker The Chair will rule on that, the product of the committee, that is the medical bill, did not exist before the House of Delegates adjourned. Therefore, the House in taking the control of that special committee from the Council is violating the by-laws.

The Speaker Will the Chairman of the Reference Committee read that resolution that has been submitted by Kings County?

Dr Stetten, Chairman Reference Committee on New Business C, New York Resolved, that the attention of the House of Delegates of the Medical Society of the State of New York be hereby directed to the failure on the part of the Council to act in accordance with a direct order of the House of Delegates at the last session with reference to the Medical Practice Act.

The Speaker That is a perfectly proper communication to bring before this House of Delegates, and we inform Dr Jennings that the Committee has reported adversely upon it, and their ground is very well taken, because it is contrary to the by-laws of this society.

Dr Rooney, Albany I rise to a point of information. Do I understand the Chair to rule that the House of Delegates exercises of itself and in itself no control over any act of the Council that may controvene or may be thought to controvene the purposes of this House of Delegates as evidenced by a resolution passed in an annual session?

The Speaker That is entirely too complicated for the Chair to answer.

Dr Rooney, Albany I think it is very plain. It merely means has the creator nothing to do with the creature?

The Speaker Dr Rooney that is not the question. The question is whether this House of Delegates can pass a resolution contrary to the constitution and by-laws. It cannot, and if it does it is null and void. That is the ruling of the Chair.

Dr Rooney, Albany May I ask another question? Wherein does the constitution settle the question of the responsibility of the Council to the House of Delegates of this Society in relation to a question such as has just been raised?

The Speaker Section 26 states "The Standing or Special Committees of the Society shall report to the Council and shall be subject to the jurisdiction of the Council at all times when the House of Delegates shall not be in session."

If there was a proposed bill reported to this House and this House acted upon that bill, then that would be binding upon the Council but the resolution creating the committee to draft a bill stated that the result of the deliberations of that committee shall supersede this section of the By-Laws. Therefore that portion of it is null and void as being contrary to the By-Laws.

Dr Rooney, Albany I rise to another point of information. The Speaker has quoted section 26. I would like to know whether that conforms with section 24, in the ruling which reads "The Council shall take such

action as is necessary to carry out the Constitution and By-Laws and to give full effect to any resolution or vote of the House of Delegates."

I, therefore, ask the Speaker how the reconciliation may be made and I think this is a very important thing.

The Speaker Between sections 24 and 26?

Dr Rooney, Albany Between sections 24 and 26. You have ruled that the Council has jurisdiction over the special and standing committees and that a resolution of this type is not in order because it is in effect asking to have attention directed to the failure of the Council, when section 24 states that the Council shall take such action as is necessary to give full effect to any vote or resolution of the House of Delegates.

The Speaker My ruling is that the reconciliation is perfect. Section 24 says the Council shall take such action as is necessary to carry out the constitution and by-laws and to give full effect to any resolution or vote of the House. If any resolution or vote of this House is contrary to any section in the Constitution and By-Laws such vote or order of the House is null and void and does not exist. Therefore it cannot be inconsistent with section 26 which is entirely a different proposition. The Speaker so rules.

Does the learned legal counsel agree with the ruling?

Mr Stryker, Legal Counsel I agree with the Speaker.

Dr Frank Jennings, Kings May I ask in view of this present ruling if the resolution at Syracuse last April or May was properly in order?

The Speaker What are you referring to, doctor?

Dr Frank Jennings, Kings The resolution which provided for the appointment of this committee as to the bill to be evolved by that committee to be the bill of the State Society.

The Speaker Why, yes. That is perfectly proper. That special committee under the order of the House of Delegates prepared a bill and under section 26 that bill which the committee prepared is under the control of the Council and the Council endorsed it.

The Speaker Are you ready for the question? Dr Stetten will read it.

Dr Stetten, Chairman Reference Committee on New Business C There is no amendment on this. The resolution is that the attention of the House of Delegates of the Medical Society of the State of New York be hereby directed to the failure on the part of the Council to act in accordance with a direct order of the House of Delegates at the last session in reference to the Medical Practice Act.

Your committee disapproved of this resolution and recommends its rejection for the reason stated.

The Speaker All those in favor of adopting the report of the committee say aye, opposed, no. Carried.

REPORT OF COMMITTEE ON MEDICAL ECONOMICS

Dr Bedell, Chairman Reference Committee on Medical Economics That part of the report referring to the nursing problem was by order of the Speaker referred to the Committee on Nursing Problems. (See page 459).

The portion referring to workmen's compensation was by similar direction referred to the Reference Committee on Legislation.

PERIODIC HEALTH EXAMINATION

Your Reference Committee approves the recommendations of said periodic examinations of apparently well person be given greater publicity. We further suggest that the enclosed physical examination record be printed in the Journal.

I move the adoption of that part of the report. Seconded and carried.

INDUSTRIAL MEDICINE IN SECTIONAL PROGRAMS

Dr Bedell, Albany We recommend that the committee on Scientific Work be requested to give as far as possible consideration to the subject of industrial medi-

time and surgery in preparing the programs of subsequent meetings.

I move its adoption. Seconded and carried.

Dr Bedell, Albany I move the adoption of the report of the report of the Committee as a whole. Seconded and carried.

TRI-STATE CONFERENCE.

The Committee, however, wishes to endorse the holding of conferences with the officers of the State Societies of New Jersey and Pennsylvania referred to in the report. (See page 422)

REPORT ON COUNCIL AND COUNCILLORS

Dr Hooly Chairman Reference Committee on Report of Council and Councillors Reference Committee on Report of Council and Councillors finds no recommendations therein requiring action by the Committee.

In the report of the Councillor of the 5th District Branch there is a suggestion that \$100.00 a year to supply means to care for District Branches is not sufficient.

The Committee feels that this suggestion is worthy of consideration. (See pages 454 and 470)

I move the adoption of the report. Seconded and carried.

REPORT OF SCIENTIFIC COMMITTEE.

Dr Humpstone Kings, Chairman of Reference Committee on Report of Committee on Scientific Work We especially commend the entire program of scientific work.

The special day's program on syphilis which has the whole-hearted support of the health activities of the entire State, and as an especial manifestation of the advantages of group studies, deserves the hearty support and attention of the whole Society.

The spirit of mutual cooperation of all departments of public health in New York State marks the splendid union of all resources in the advance of scientific work.

It was moved and seconded the report of the committee be adopted. Carried. (See page 436)

REORGANIZATION OF SOCIETY'S OFFICE.

Dr Courten, Queens, Chairman Reference Committee on Reports of Secretary and Treasurer

On page seven in paragraph 3 under the "Society's Office," there is a recommendation to organize three separate departments to cover respectively the secretarial, financial and editorial activities of the secretary's office, each having its own staff, correlated to the business manager. In view of the Society being about to move into its new quarters we would recommend that this suggestion be carried out under the direction of the secretary and subject to the approval of the Council and that funds for the refurnishing of the new office be provided therefor. (See page 423)

Dr Dougherty, Secretary In my report—it was really not a report but a survey of the financial situation of the Society—there were no recommendations. It was a suggestion, and, furthermore, the recommendation of the Committee regarding an appropriation could not be passed by the House of Delegates. Appropriation can only be made by the Council or the Executive Committee for the Council.

The Speaker Will you make those corrections?

Dr Courten, Queens I withdraw the portion that refers to the financing of the proposition and recommendations.

Dr Dougherty, New York Secretary This was a

survey more to lay before the Society the conditions and situations, with suggestions of what should be done by my successor in order to bring affairs into a more modern, business-like condition.

The Speaker Are you ready for the question? All those in favor of adopting the amended report of the Secretary, signify by saying aye, opposed, no. Carried.

COMMITTEE ON MEDICAL EDUCATION

Dr Podvin, New York Chairman Reference Committee on Report of Committee of Public Health and Medical Education

Your Reference Committee on "Report of Committee of Public Health and Medical Education" respectively submits the following report. (See page 427)

We approve and commend the excellent work done by Dr Gordon and his Committee. I moved its adoption submits the following report.

We approve the request of the Committee and recommend that they be authorized to accept funds from other agencies for further extension of their work.

We recommend the employment of a full time medical man to carry out the work of this Committee, and we further recommend the appropriation of a sum sufficient to cover the salary of this full time man and \$5,000 five thousand dollars, additional for the expenses of the Committee.

The sum of five thousand dollars is the amount of money that was provided for the use of this committee last year, so that the recommendation is really for the same amount for next year, with the addition of a whole-time man.

The Speaker The Chairman of the Committee will strike the appropriation out of his report.

ACCEPTING EDUCATIONAL FUNDS FROM OUTSIDE SOURCE.

Dr Podvin We approve the request of the Committee and recommend that they be authorized to accept funds from other agencies for further extension of their work.

Dr Kopetzky, New York I move it be referred to the Council for action. Seconded and carried.

Dr Halsey, New York I would like to move a reconsideration of the report which was referred to the Council. Seconded.

Dr Halsey Yes I should like to have that amended so that it recommends to the Council that they make it possible that the committee can have the charge of such funds. Seconded.

The Speaker It is moved and seconded and carried that the report referred to the Council be reconsidered. Now, the original motion before you. Dr Halsey, will you state your amendment?

Dr Halsey The amendment was that it be recommended to the Council that they make it possible for that committee to have outside funds put at their disposal.

The Speaker The proposed amendment is "that we approve the request of the committee and recommend that they be authorized to accept the funds from other agencies for the further extension of their work be amended "that the Council make it possible for that Committee to have outside funds put at their disposal."

Dr Rooney, Albany I think this is too important to settle a few moments before adjournment. I move you therefore, that the question be postponed to be the first order of business at the adjourned session this evening.

The Speaker Any discussion? If not all those in favor say aye, those opposed, no. Carried. Page 470.

Dr Frank Jennings Kings I move we adjourn until eight o'clock. Seconded and carried.

EVENING SESSION, MONDAY, MARCH 29, 1926

The meeting was called to order by the Speaker at 8 P M

ADDRESS BY HON BIRD S COLER

The Speaker We have with us tonight the Commissioner of Public Welfare of the City of New York and I will ask him to address you I introduce the Honorable Bird S Coler

Hon Bird S Coler Dr Harris, ladies and gentlemen I really did not expect this honor when I dropped up here this afternoon I thought I was going to meet some of the friends I met through the state and get our friendship a little bit more closely articulated, because if we do not hang together we are going to hang separately on some problems

I want to express the very great appreciation we have of the medical profession, and all that our department and all the city hospitals owe to it. It has never been served by a more loyal and better type of men and we believe in dealing with our medical boards and supporting them

There is going to be a lot of discussion in New York City over hospitals in the next few months and it is well always for us to have our feet on the ground We are going to have discussion as to whether the state ought to go into the practice of medicine entirely and whether the hospitals should be run for the rich as well as the poor, and the doctors to be paid standard salaries and socialized That will be one end of it I happen to be on the other phase of it The discussion will become rather acute and will be brought up in a very clever and most surreptitious way It is only a great organization like yours that can watch it I do not believe that you can socialize brains Brains have to have an opportunity to earn what they are worth, and the minute you attempt to force them it will put the profession where it will not be with a real earning capacity I am not going into that

I want to thank your organization for its report on the nursing situation I could talk to you two or three hours on this subject but I am not going to do so The time will come when we shall have to put a nurse who will nurse a patient who is sick in bed on a pedestal We are today worshipping types of nurses who do not take care of the sick, and we have got to make the nurse who really does take care of the sick as respectable as the nurse who does not We see this very clearly in our hospitals We are compelled to take care of sick people Even if anyone of you gentlemen should unfortunately happen to be struck by an automobile or something else in the street we would have to pick you up and take care of you, and we have got to have equipment ambulances, and nurses to take care of you So while we believe in nursing education we do not believe that the hospital should be made an appendage to a nursing school or any other kind of school We believe the care of the patient should come first

As the discussion to which I referred comes along we are going to stand by the medical profession

If we can get a bill or a rule passed whereby we can make a good first-class trained nurse and then give her an opportunity to go up higher or lower on the scale as we think best, a nurse who will take care of the sick the Department of New York City will set aside one of our great institutions the minute this is done and start in developing a good bedside nurse and put a medal on her for being a good bedside nurse

I thank you all, and if you want to visit any of our institutions during your stay they will be at your disposal I thank you again very much for this opportunity to say the few words that I have to you

The Speaker Is Podvin Chairman of Committee on Report of Committee on Public Health and Medical Education in the room?

Dr Rooney, Albany The committee is sitting in the ante-room

The Speaker Dr Rooney I will appoint you a committee of one to report to the Speaker when the Committee will be ready to report because that report is a special order of business

Dr Rooney, Albany The committee has asked me to say that they desire more time

The Speaker Will you move the reconsideration of that special order?

Dr Rooney, Albany I move that the motion that I made this afternoon in relation to making the report of this Committee the first order of business at the evening session be reconsidered Seconded and carried.

Dr Rooney, Albany I move that the House proceed to the regular order Seconded and carried.

PRESIDENT'S ADDRESS

Dr Soudern New York Chairman Reference Committee on President's address Page 420

"Your committee reads with satisfaction the President's reference to the growing activities of the Society and would endorse the recommendation that a firm of efficiency and accounting experts be retained to study the needs and equip the Society with a complete modern business system"

Dr Dougherty New York, Secretary I move that be referred to the Council. Seconded and carried.

THE JOURNAL.

Dr Soudern "The commendation voiced in the report relative to the Journal is considered fully deserved and has our endorsement Dr Wightman is to be congratulated on the success achieved in so brief a period

COUNSEL.

As the Chairman of your Reference Committee had much to do with the original appointment of George W Whiteside as Counsel of the Society he would stress his regret together with a regret of the other members of the Committee on learning of his resignation Your Committee begs leave to recommend to the Council of the Society or probably to the House of Delegates an official expression of appreciation, and engrossed copy of which shall be sent to Mr Whiteside." Seconded

The Speaker You have heard that recommendation.

Dr Dougherty, New York, Secretary The Council has already taken suitable action in regard to Mr Whiteside's resignation They were to send him a copy of it

The Speaker Engrossed?

Dr Dougherty, New York, Secretary No

Dr Bedell, Albany I move you, sir, that it come from the House of Delegates, a much larger and more representative body

The Speaker It is moved and seconded that that portion of the report that relates to the House of Delegates sending this engrossed resolution to Mr Whiteside be added to the report. All those in favor say aye, opposed, no Carried

The Speaker All those in favor of the recommendation of the Committee as amended say aye, opposed, no Carried

Next recommendation

Dr Soudern "There is a sense of satisfaction to your Committee in the knowledge that Mr Whiteside is to be succeeded by Mr Lloyd Stryker who has at his command the original office staff

The President's reference to the question of legal defense and insurance is one which deserves the earnest consideration not only of every member of this House of Delegates but of every member of the State Society. Malpractice suits are on the increase, that defense for uninsured members is a burden of the Society of no small moment, and your Committee recommends that it shall be the sense of this House of Delegates to urge upon every member in practice, the carrying of a suitable policy for his own protection as well as to save the Society the expense of defending him in case of need The moral support of the Society is his in any event and its members serve him as experts without pay in any event—but this is in the final analysis all that he shall ask" Seconded

The Speaker You have heard the recommendation All those in favor say aye, opposed no Carried

Dr Soudern "The commendation on the work of the various committees is an evidence of a wise selection of

men for the purpose. The details of the work done by those committees will be covered by the Reference Committee directly assigned

Your committee begs for your endorsement of the Resolution of the Executive Committee of January 14, 1926, when the President appointed a committee to aid in the carrying out of a preventive medicine campaign, to, among other things, make toxin-antitoxin available to every child in the State of New York, and mind you, to place the responsibility for its distribution upon the medical profession of the State and not in the hands of a favored few"

I recommend its adoption. Seconded and carried
Dr Sondern "The views of the President relative to legislation should have your endorsement, the details are however in the hands of the Reference Committee especially concerned.

TRI-STATE CONFERENCE.

The Tri-State Conference report by the President also deserves your support in the opinion of your Committee" Seconded and carried. (See page 422)

DEATHS OF DRS SUITER AND WENDE.

Dr Sondern "When the House of Delegates has expressed its sorrow in the sad loss of Dr A Walter Suiter and Dr Grover W Wendt, it is the sense of your Committee that suitably inscribed resolutions shall be adopted which shall go to the bereaved families of the former presidents of the Society"

APPRECIATION OF PRESIDENT VAN ETEN

Dr Sondern "In closing your Committee wishes to express to the House of Delegates its appreciation of the sterling qualities and singular fitness of the retiring president, Dr N B Van Etten"

Dr Sondern I move the adoption of the amended report as a whole. Seconded and carried

MALPRACTICE DEFENSE.

Dr Townsend, Chairman Reference Committee on Report of Legal Counsel We endorse the portion in the report which pays tribute to the splendid qualities of Mr George W Whiteside and congratulate the Society on obtaining a Counsel already seasoned and experienced in the legal problems peculiar to our profession to finish Mr Whiteside's unexpired term

Analysis of Table I shows that one-half as many suits are disposed of as instituted in the year, thus increasing to 355 the suits pending on February 1, 1926. Of the 66 suits disposed, in only five were judgments given against a physician. These figures bespeak attention to detail and thorough preparation of the cases prior to trial

The counsel's caution of increasingly larger awards by juries prompts your committee to again remind our members that the society defends but does not indemnify

Your committee expresses its gratification on the increased percentage of members insured and expresses the hope that the percentage will materially increase each year We furthermore hope that each delegate will use his influence to induce those uninsured to join in our group plan of insurance.

Your committee feels that the thanks of the Society should be tendered to counsel for his editorials and the digest of cases tried, woo, and lost. We hope that these reports will continue to appear in the columns of the State Journal

Your committee commends the counsel's activities in correspondence, attending meetings, and his liberal expenditure of time and energy for the Society's benefit.

Your committee feels that the Society's thanks are due Mr Oliver for his professional assistance and to Mr Wanvig for his co-operation and assistance in handling the cases arising under the group plan of insurance"

I move the adoption of the report

Seconded and carried

REPORT OF COMMITTEE ON LEGISLATION.

Dr John Jennings, Kings, Chairman Reference Committee on Report of Committee on Legislation The Reference Committee on the Report of the Committee on Legislation recommends the acceptance of the Report and submits the following comments Page 431

Your Committee endorses the Legislative Committee's interest in securing the Cooperation of "lay organizations" having the interest in health matters and hopes that this cooperation may thrive and flourish until the ideals of medicine and the aspiration of welfare completely coincide. They belong together It is our belief however that no opportunity should be lost, not even this one, to express the fact that the Doctors dread of socialism is based on no selfish motive but on the well grounded assurance that in the perpetuation and perfection of the personal relation of physician and patient lies the best hope of public as well as individual health.

Your Committee notes with approval the passage of the Trustees bill, now a law, and would question the nature and objects of the law providing for the establishment and conduct of Nurse Registries.

This is not the time to discuss the attempt of the House of Delegates of 1925 to construct a medical practice act Such an attempt was made however and the report of the Committee appointed to prepare such an act is in your hand.

The Report of the Committee on Legislation states that "after the committee's amendment of the Medical Practice Act was accepted by the Council and the State Department of Education we were encouraged through our contacts in the Legislature to believe that our efforts this year would meet with success"

It seems only fair to the Committee directed to draw up the Act and to the bill as reported to you by that Committee to draw attention to the fact that the amendments made by the Legislative Committee materially alter and in fact change the essential intent of the original bill.

The present conditions in the Legislature, your Committee is informed, render the passage of the so-called Miller Bill most improbable, so that a discussion of its provisions may seem unnecessary at this time. However, it embodies an expression of opinion and outlines a policy of the State Society which your Committee hesitates to endorse.

It may be conceded that practice under the Workmen's Compensation Act is not at present satisfactory but your Committee does not agree that the Medical Society of the State of New York should attempt to engage in the problem so intimately as is suggested.

The present system of Compensation law which denies to the injured workman his right to choose his own physician from those endorsed as competent and licensed to practice by the State of New York cannot be acceptable to a free man white or black.

The problem has not been solved, it calls for re-statement and re-solution

The suggestion of the Committee that one or two meetings of the Chairman of the Legislative Committees of the County Societies be held during the legislative session is another contribution to the attempt to secure unanimity or to limit dissent to the Society's legislative activities

So long as the Legislation program of the Society is limited to the obstruction of unsafe or unwise legislation and so long as no fixed policy of constructive reform is desired by the Society such a course seems fair enough

The Society needs, however, a mechanism for the formulation as well as the execution of its legislative program which we are persuaded should be comprehensive construction fully cognizant of existing evils and aggressively interested in their correction.

The Legislative policy of the Medical Society of the State of New York should express its own interest."

I move its adoption. Seconded.

The Speaker Are you ready for the question? The

EVENING SESSION, MONDAY, MARCH 29, 1926

The meeting was called to order by the Speaker at 8 P M

ADDRESS BY HON BIRD S COLER

The Speaker We have with us tonight the Commissioner of Public Welfare of the City of New York and I will ask him to address you I introduce the Honorable Bird S Coler

Hon Bird S Coler Dr Harris, ladies and gentlemen I really did not expect this honor when I dropped up here this afternoon I thought I was going to meet some of the friends I met through the state and get our friendship a little bit more closely articulated, because if we do not hang together we are going to hang separately on some problems

The Speaker You have heard the recommendation All those in favor say aye, opposed, no Carried

Dr Sandern "The commendation on the work of the various committees is an evidence of a wise selection of

The Speaker Then you read further down in Article VIII "Nor shall any indebtedness be incurred by any officer, committee or member of committee of the Society as a charge against the Society until the same shall have been approved by the "Board of Trustees," instead of "Council" Seconded and carried unanimously

Dr Sloan Under Section 6 of the By-Laws, after "(c)" add "Trustees"

The Speaker Section 6 will then read "The House of Delegates shall be composed of (a) delegates elected by the component County Medical Societies, (b) officers of the Society", and adding "(c) Trustees," and, of course, the other lettering will be arranged according

Dr Phillips, New York Does the resolution say the members of the Board of Trustees are members of this house with vote?

The Speaker If you look on page two of your folder you will see under By-Laws "Section 6, line 4, after the semi-colon (;), insert the word "(c) the trustees" Now, that would make Section 6 read "The House of Delegates shall be composed of (a) Delegates elected by the component County Medical Societies, (b) officers of the Society, (c) trustees," and, therefore, that amendment makes them members of the House of Delegates with vote. If you wish to modify that so they will be members of the House without vote, you can make that amendment

Dr Bedell, Albany I move that amendment, that the trustees be members of the House of Delegates without vote.

The Speaker The proposed amendment by Dr Bedell is that the trustees be members of the House of Delegates without vote Motion seconded

Dr Ludlum, Kings An amendment to the amendment would simplify the expression Bracket (d) in the old By-Laws says "the past presidents of the Society shall be life members with voice but without vote." I wonder if this could not be put after that —

The Speaker It could be done very nicely Will you do it?

Dr Ludlum Kings I move that amendment

The Speaker Dr Bedell will you accept it?

Dr Bedell, Albany Yes

The Speaker Are you ready for the amendment as proposed by Dr Ludlum and accepted by Dr Bedell? All in favor please say "aye" opposed "no" Carried

Dr Sloan Oneida Section 12, after line 12, insert a new line 13 to read "8, Report of the Trustees" I move its adoption.

The Speaker The order of business is changed to put in Trustees All those in favor say aye, opposed, no Carried unanimously

Dr Slaan, Oneida Section 13, after the word "officers" add the word "trustees," and after the word "officers" in the third line before the last add "trustees", so that the section will read "The officers, trustees, and Chairman of committees of the Society" and ending "no member of the Society shall be eligible for any office or entitled to vote for any officer, trustee, chairman of standing committees or delegates who is in arrears for county dues and state Society per capita assessment."

I move its adoption Seconded

The Speaker You are voting on Section 13 "The officers—" and you insert the word "trustees" so it will read "the officers, trustees and chairman of committees of the Society, to be elected by the House of Delegates shall be elected at an adjourned session of the annual meeting of the House of Delegates, which adjourned session shall be held at a convenient hour on the first day of the annual meeting of the Society No member of the Society shall be eligible for any office or entitled to vote for any officer or trustee, chairman of standing committees or delegates who is in arrears for county dues and State Society per capita assessment."

There are two places in that section in which the word 'trustees' is added Are you ready for the question?

All those in favor of that say aye, opposed, no Carried unanimously

Dr Slaan, Oneida Section 14, line 3, before the word "censors" insert the word "trustees" I move the adoption of that amendment. Seconded.

The Speaker You are voting on the amendment. All those in favor say aye, opposed, no Carried unanimously

Dr Sloan In Section 23 strike out the words "Shall have charge of all properties and the financial affairs of the Society and." Which means that the duties are transferred from the Council to the Board of Trustees Seconded and carried.

Dr Sloan, Oneida Section 25 of the By-Laws is deleted and I so move.

The Speaker It reads "All moneys of the Society received by the Council or any member or agent thereof shall be paid to the Treasurer of the Society The Council shall approve the bond of the Treasurer as to amount, form and surety, it shall employ a public accountant to audit the accounts of the Treasurer and Secretary and other agents of the Society and present a statement of the same in its annual report to the House of Delegates The Council shall make a report to the House of Delegates of its transactions for the year and of the amount of money belonging to the Society under its control."

Therefore, it is moved by the Chairman of the Committee to strike that out as he will present a new section to replace it in which the "Board of Trustees" in stead of the "Council" having charge of the funds of the Society Seconded

Are you ready for that question? All those in favor say aye, opposed, no Carried unanimously It is stricken out.

This is the substitute for that Section 25

Dr Slaan, Oneida Section 33 At the first meeting of the Board of Trustees following the annual meeting of the House of Delegates, it shall organize and elect a chairman The Board of Trustees shall hold regular meetings at times and places that shall be fixed by the Chairman of the Board of Trustees and any three members of the Board of Trustees may require the Chairman thereof to call a meeting at the office of the State Society for such time as shall be designated by them in writing, of which the members of the Board shall have at least seven days' notice. I move its adoption

The Speaker All those in favor of Section 33 as read by the chairman say aye, all those opposed, no Carried unanimously

Dr Slaan, Oneida Section 34 The Board of Trustees shall have charge of all property including trust funds and shall manage the financial affairs of the Society and shall invest the surplus from time to time. The budget prepared by the Executive Committee shall be submitted to the Board for its approval and all resolutions or recommendations of the House of Delegates, Council or Executive Committee pertaining to appropriation of money must be approved by the Board of Trustees before the same shall become effective.

I move its adoption. Seconded.

The Speaker You notice the word "appropriation" is used so that you may make appropriations subject to the approval of the Board of Trustees before they become effective.

Are you ready for the question?

Dr Vander Veer, Albany Will you read that again? I think that takes away from the House of Delegates the power to expend money, does it not?

The Speaker The House of Delegates has no power to expend money now

Dr Vander Veer, Albany All right.

The Speaker It merely takes it away from the Council and puts it in the Board of Trustees so that the Council will have no right to expend money

Are you ready for that question? All those in favor say aye, opposed no Carried unanimously

Dr Sloan Oneida Section 35 All moneys of the Society received by the Board of Trustees, Council or

question is on the adoption of the report of the chairman of the Reference Committee on Legislation. All those in favor say aye, opposed, no. Seconded and carried.

ENDORSEMENT OF MEDICAL PRACTICE ACTS (Continued from page 461)

Dr Stetten, Chairman Reference Committee on New Business C "Your Reference Committee on New Business C disapproves of the Resolution proposed by the Medical Society of the County of Kings, which reads:

RESOLVED, That the State Legislative Committee shall not endorse or approve in the name of the Medical Society of the State of New York any medical practice act or amendment thereto, without referendum to the component County Medical Societies following notification to every member of the State Society by prompt publication of proposed legislation in the "New York State Journal of Medicine" or a bulletin thereof.

Your Committee disapproves of this resolution because of its wording but approves of its general basic principles and therefore submits a substitute resolution which is as follows:

RESOLVED, That before approval or endorsement in the name of the Medical Society of the State of New York by the Council or Legislative Committee of proposed legislation affecting the Public Health Law in relation to the practice of medicine, such proposed legislation shall be submitted for referendum to the component medical societies following publication thereof in the New York State Journal of Medicine and that when said legislation be approved by a two-thirds vote of the County Societies voting it shall be subject only to such changes as are approved by the Council and Legislative Committee.

Your committee moves the adoption of this resolution." Seconded.

The Speaker Are you ready for the question? All those in favor of the adoption of the report of the Committee as read will signify by saying aye, and those who are opposed will say "no." The motion is lost.

Dr Dougherty, Secretary, New York I ask for a division.

The Speaker The Secretary will read the report of the committee.

Dr Dougherty, Secretary, New York "Your Reference Committee on New Business C disapproves of the Resolution proposed by the Medical Society of the County of Kings which reads:

RESOLVED, That the State Legislative Committee shall not endorse or approve in the name of the Medical Society of the State of New York any medical practice act or amendment thereto, without referendum to the component County Medical Societies following notification to every member of the State Society by prompt publication of proposed legislation in the "New York State Journal of Medicine" or a bulletin thereof.

Your Committee disapproves of this resolution because of its wording but approves of its general basic principles and therefore submits a substitute resolution which is as follows:

RESOLVED, That before approval or endorsement in the name of the Medical Society of the State of New York by the Council or Legislative Committee of proposed legislation affecting the Public Health Law in relation to the practice of medicine, such proposed legislation shall be submitted for referendum to the component medical societies following publication thereof in the "New York State Journal of Medicine" and that when said legislation be approved by a two-thirds vote of the County Societies voting it shall be subject only to such changes as are approved by the Council and Legislative Committee.

Your Committee moves the adoption of this Resolution."

The Speaker That substitute resolution has been put to a voice vote and the Speaker declared that it was lost. Now, a division has been called for and any member has

a right to demand it without being seconded. Therefore, I will ask those who are in favor of that resolution to rise. The Secretary announced twenty-five in favor of the adoption of the resolution and seventy-seven against it. *The Speaker* The Speaker declares the resolution lost.

All those in favor of the original resolution say aye, opposed, no. Lost.

BOARD OF TRUSTEES

Dr Sloan, Oneida, Chairman of the Reference Committee on Speaker's address, Constitution and By-Laws recommends the adoption of the following to be known as Article 6 of the Constitution:

ARTICLE VI

"The Board of Trustees shall consist of five members elected as such Trustees, and the President, the Speaker and the Secretary shall be members of the Board of Trustees with voice but without vote.

"In 1926 one Trustee shall be elected for five years, one for four years, one for three years, one for two years and one for one year and thereafter, one trustee shall be elected annually for a period of five years.

I move the adoption of that section of the report. Seconded. Carried unanimously.

Dr Sloan, Oneida, Your Committee recommends a modification of Article 8 of the Constitution striking out the word "appropriated" and supplying the word "expended," so as to read "No funds of the Society shall be expended for any purpose except by authority of a resolution of the Board of Trustees, nor shall any indebtedness be incurred by any officer, committees or members of committees of the Society as a charge against the Society until the same shall have been approved by the Board of Trustees."

The Speaker This article strikes out the Council having authority over the funds of the Society and transfers it to the Board of Trustees and changes the word appropriated to expended. Seconded.

The Speaker Are you ready for the question?

Dr Rooney, Albany As I heard the Chairman of the Reference Committee, he made the statement concerning striking out the word "appropriated" and insert the word "expended." I do not see that exact word in here.

The Speaker Simply that the Trustees who are expending the money are substituted in place of the Council and the word appropriated was changed to expended. That would give the House the privilege to recommend appropriations subject to the approval of the Board of Trustees.

Dr Rooney, Albany I would like to have the opinion of the Counsel of the State Society. Is it possible without notice of this specific amendment to amend the By-Laws in this way, by changing a word without previous notice?

The Speaker It is merely to conform to the changes made in the Constitution and By-Laws which provide for the Board of Trustees.

Mr Oliver, Attorney Notice having been given at the meeting in 1925 of a change in the section, in my opinion that can be amended by substituting the word "expended" for the word "appropriated" by an amendment from the floor.

Dr Rooney, Albany That is if notice is given that an article will be amended in a certain specific way, in a notice as provided in the by-laws, thereafter that proposed specific amendment opens up the whole article to amendment without notice from the floor?

Mr Oliver That is true, and the exact language of the notice need not be adopted but other language may be adopted after discussion from the floor.

The Speaker That no funds of the Society shall be expended for any purpose except by the authority of a resolution of the Board of Trustees, is the question. Seconded and carried unanimously.

The Speaker Then you read further down in Article VIII "Nor shall any indebtedness be incurred by any officer, committee or member of committee of the Society as a charge against the Society until the same shall have been approved by the "Board of Trustees," instead of "Council" Seconded and carried unanimously.

Dr Sloan Under Section 6 of the By-Laws, after "(c)" add "Trustees"

The Speaker Section 6 will then read "The House of Delegates shall be composed of (a) delegates elected by the component County Medical Societies, (b) officers of the Society", and adding "(c) Trustees," and, of course, the other lettering will be arranged according

Dr Phillips, New York Does the resolution say the members of the Board of Trustees are members of this house with vote?

The Speaker If you look on page two of your folder you will see under By-Laws "Section 6, line 4, after the semi-colon (;) insert the word "(c) the trustees" Now, that would make Section 6 read "The House of Delegates shall be composed of (a) Delegates elected by the component County Medical Societies, (b) officers of the Society, (c) trustees," and, therefore, that amendment makes them members of the House of Delegates with vote. If you wish to modify that so they will be members of the House without vote, you can make that amendment

Dr Bedell, Albany I move that amendment, that the trustees be members of the House of Delegates without vote.

The Speaker The proposed amendment by Dr Bedell is that the trustees be members of the House of Delegates without vote Motion seconded

Dr Ludlum, Kings An amendment to the amendment would simplify the expression Bracket (d) in the old By-Laws says "the past presidents of the Society shall be life members with voice but without vote." I wonder if this could not be put after that —

The Speaker It could be done very nicely Will you do it?

Dr Ludlum, Kings I move that amendment

The Speaker Dr Bedell will you accept it?

Dr Bedell, Albany Yes

The Speaker Are you ready for the amendment as proposed by Dr Ludlum and accepted by Dr Bedell? All in favor please say "aye," opposed, "no" Carried

Dr Sloan Oneida Section 12, after line 12, insert a new line 13 to read "8, Report of the Trustees" I move its adoption

The Speaker The order of business is changed to put in Trustees All those in favor say aye, opposed, no Carried unanimously

Dr Sloan, Oneida Section 13, after the word "officers" add the word "trustees," and after the word "officers" in the third line before the last add "trustees", so that the section will read "The officers trustees and Chairman of committees of the Society" and ending "no member of the Society shall be eligible for any office or entitled to vote for any officer, trustee, chairman of standing committees or delegates who is in arrears for county dues and state Society per capita assessment."

I move its adoption Seconded

The Speaker You are voting on Section 13 "The officers—" and you insert the word "trustees" so it will read "the officers, trustees and chairman of committees of the Society, to be elected by the House of Delegates shall be elected at an adjourned session of the annual meeting of the House of Delegates which adjourned session shall be held at a convenient hour on the first day of the annual meeting of the Society No member of the Society shall be eligible for any office or entitled to vote for any officer or trustee, chairman of standing committees or delegates, who is in arrears for county dues and State Society per capita assessment"

There are two places in that section in which the word "trustees" is added Are you ready for the question?

All those in favor of that say aye, opposed, no Carried unanimously

Dr Sloan, Oneida Section 14, line 3, before the word "censors" insert the word "trustees." I move the adoption of that amendment. Seconded.

The Speaker You are voting on the amendment. All those in favor say aye, opposed, no Carried unanimously

Dr Sloan In Section 23 strike out the words "Shall have charge of all properties and the financial affairs of the Society and." Which means that the duties are transferred from the Council to the Board of Trustees Seconded and carried

Dr Sloan, Oneida Section 25 of the By-Laws is deleted and I so move.

The Speaker It reads "All moneys of the Society received by the Council or any member or agent thereof shall be paid to the Treasurer of the Society The Council shall approve the bond of the Treasurer as to amount, form and surety, it shall employ a public accountant to audit the accounts of the Treasurer and Secretary and other agents of the Society and present a statement of the same in its annual report to the House of Delegates The Council shall make a report to the House of Delegates of its transactions for the year and of the amount of money belonging to the Society under its control."

Therefore, it is moved by the Chairman of the Committee to strike that out as he will present a new section to replace it in which the "Board of Trustees" in stead of the "Council" having charge of the funds of the Society Seconded.

Are you ready for that question? All those in favor say aye, opposed, no Carried unanimously It is stricken out.

This is the substitute for that Section 25

Dr Sloan, Oneida Section 33 At the first meeting of the Board of Trustees following the annual meeting of the House of Delegates, it shall organize and elect a chairman The Board of Trustees shall hold regular meetings at times and places that shall be fixed by the Chairman of the Board of Trustees and any three members of the Board of Trustees may require the Chairman thereof to call a meeting at the office of the State Society for such time as shall be designated by them in writing, of which the members of the Board shall have at least seven days' notice. I move its adoption.

The Speaker All those in favor of Section 33 as read by the chairman say aye, all those opposed, no Carried unanimously

Dr Sloan, Oneida Section 34 The Board of Trustees shall have charge of all property including trust funds and shall manage the financial affairs of the Society and shall invest the surplus from time to time. The budget prepared by the Executive Committee shall be submitted to the Board for its approval and all resolutions or recommendations of the House of Delegates, Council or Executive Committee pertaining to appropriation of money must be approved by the Board of Trustees before the same shall become effective.

I move its adoption. Seconded.

The Speaker You notice the word "appropriation" is used so that you may make appropriations subject to the approval of the Board of Trustees before they become effective.

Are you ready for the question?

Dr Vander Veer Albany Will you read that again? I think that takes away from the House of Delegates the power to expend money, does it not?

The Speaker The House of Delegates has no power to expend money now

Dr Vander Veer, Albany All right.

The Speaker It merely takes it away from the Council and puts it in the Board of Trustees so that the Council will have no right to expend money

Are you ready for that question? All those in favor say aye opposed, no Carried unanimously

Dr Sloan Oneida Section 35 All moneys of the Society received by the Board of Trustees, Council or

any member or agent thereof shall be paid to the Treasurer of the Society. The Board of Trustees shall approve the bond of the Treasurer as to amount, form and surety, it shall employ a public accountant to audit the accounts of the Treasurer and Secretary and other agents of the Society and present a statement of the same in its annual report to the House of Delegates. The Chairman of the Board of Trustees shall make a report to the House of Delegates of its transactions for the year and of the amount of money belonging to the Society under its control."

I move the adoption of Section 35. Seconded.

The Speaker Are you ready for the question? All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 36 "Three members of the Board of Trustees shall constitute a quorum."

I move the adoption of that. Seconded.

The Speaker All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 37 The following shall be the order of business at meetings of the Board of Trustees

One Calling the meeting to order

Two Roll call by the Secretary

Three Reading of minutes

Four Communications

Five Reports

Six Unfinished business

Seven New Business

I move its adoption. Seconded.

The Speaker All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida In Section 37 after the word "council" insert "Board of Trustees." I move its adoption. Seconded.

The Speaker All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida The fourth line from the bottom Section 37, for the word "council" substitute "Board of Trustees." Seconded.

The Speaker All those in favor of that modification say aye, opposed, no. Carried unanimously.

Dr Sloan Section 23 Strike out the words shall have charge of all properties and the financial affairs of the Society and which means that the duties are transferred from the Council to the Board of Trustees. Seconded. Carried.

Dr Sloan Section 39 For "Council or Executive Committee" substitute "Board of Trustees," fourth line. Seconded.

The Speaker All those in favor of that say aye, opposed, no. Carried.

Dr Sloan Section 39 Seventh line. Change the word "president" to "Chairman of the Board of Trustees." Seconded.

The Speaker All those in favor of that change say aye, opposed, no. Carried unanimously.

Seventh line from the bottom, change the word Council to Board of Trustees. Seconded and carried.

The Treasurer shall be a trustee of the Merritt H. Cash Fund, the Lucien Howe Fund, and such other special funds as may be established" is stricken out because all those funds are provided for in the custody of the Board of Trustees instead. Seconded.

The Speaker All those in favor of that say aye, opposed, no. Carried unanimously.

"The treasurer shall make an annual report to the House of Delegates and then in addition to the Board of Trustees whenever requested"—that is added. Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

The Speaker "The salary of the treasurer," it says, "shall be fixed by the Council." The word "Council" is to be stricken out and "The Board of Trustees" inserted. Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 42. The second sentence strike out "the members of the Council" and insert "the members of the Board of Trustees." Seconded.

The Speaker This provides that trustees be allowed railroad fares for attending the meetings. All those in favor say aye, opposed, no. Carried unanimously.

Section 42 provides that proper vouchers must be filed with the secretary and approved by the Executive Committee. "The Executive Committee" is stricken out and "The Board of Trustees" inserted. Seconded.

All those in favor say aye, opposed, no. Carried.

Section 42 states "the vouchers of such expense shall be approved by the Executive Committee." Strike out "Executive Committee" and insert "trustees." Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Section 42 reads "provided a proper statement of such expense shall have been presented to the secretary and approved by the Executive Committee." Strike out "Executive Committee" and insert "trustees." Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Section 42 provides "This time may be extended for any cause by the Council or Executive Committee." "Council or Executive Committee" is stricken out and "Board of Trustees" inserted. Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 66. After the "House of Delegates, Council" insert "Board of Trustees." Insert "Board of Trustees" after the word "Council." Seconded.

The Speaker These are the notices for the annual meeting. All those in favor of that say aye, opposed, no. Carried unanimously.

Instead of ten days' notice in order to have these all covered by the same blanket article, the House of Delegates and the Council and the Board of Trustees are all to be allowed seven days' notice instead of ten. Seconded.

All those in favor of that say aye, opposed, no. Carried unanimously.

BOARD OF CENSORS

The Speaker Article VI reads "The President, the Secretary, and the eight district councillors shall be known as the Board of Censors. The House shall elect them annually." It is moved to strike out the words "The House of Delegates shall elect them annually." Seconded.

The Speaker All those in favor of the adoption of that amendment say aye, those opposed, no. Carried unanimously.

Section 17 says the censors shall be nominated as provided in Article 6 of the Constitution and elected by a majority vote without debate. That should be stricken out. Seconded.

Those in favor of striking that out (Section 17) say aye, opposed, no. Carried unanimously.

The Speaker Strike out censors, third line, Section 14. Carried unanimously.

DELEGATE TAKES OFFICE

The Speaker Dr Wightman introduced last year an amendment to the by-laws which is reported in the proceedings of the House of Delegates, that the term of a delegate of a county Medical Society shall begin at the first annual meeting of the House of Delegates subsequent to his election. Dr Wightman's amendment shall be added at the end of section 19, as follows "The term of a delegate elected by a County Medical Society shall begin at the first annual meeting of the House of Delegates subsequent to his election." Now, Dr Wightman was appointed a committee of one to think over this amendment and present it or a substitute. He has

thought over it a whole year and he has presented the same one he presented last year. So I ask your adoption of it. Seconded.

The Speaker All those in favor of the amendment of Dr Wightman will signify by saying aye, those opposed, no. Carried.

FILLING VACANCIES

Dr Sloan The next is Section 24 "When the House of Delegates is not in session, the Council shall have power to fill any vacancy which may occur in any elective office." Now, since we have trustees who are holding office for five years, this recommendation has been made by the Committee.

The Speaker The section as amended will read "The Council shall have power to fill any vacancy which may occur in any elective office not otherwise provided for until the next annual meeting of the House of Delegates." Seconded.

Those in favor say aye, opposed, no. Carried unanimously.

PRESIDENT ELECT

All those in favor that the president-elect be added to the officers say aye, opposed, no. Carried unanimously.

ASSISTANT SECRETARY AND TREASURER

Dr Sloan We have an amendment to Article 4 of the constitution by striking out the word "except" and in place add the word "including" the assistant secretary and the assistant treasurer. The object of that is to add the assistant secretary and the assistant treasurer to the Council. Seconded.

The Speaker All those in favor say aye, opposed, no. Carried unanimously. (For further amendments see page)

Dr Bedell, Albany I move we adjourn to meet at 9 A M tomorrow. Seconded and carried.

Thereupon the meeting was adjourned to resume at 9 o'clock A. M., March 30, 1926.

ADJOURNED MEETING OF THE HOUSE OF DELEGATES

TUESDAY, MARCH 30, 1926

The meeting was called to order by the Speaker at 9 A M.

ELECTION OF OFFICERS

The Speaker The first order of business is the election of officers, and now that we have adopted the by-laws which provides for trustees, it is necessary to pass a resolution as to the method of their election. The Reference Committee on Constitution and By-Laws and the Speaker's address reports the following resolution for your consideration, and with the consent of the Chairman, Dr Sloan, I will read it and put it up to you for action, namely

"Resolved That nominations shall be made for at least five trustees. The trustee receiving the highest number of votes shall be elected for five years, the next highest for four years, the next highest for three years, the next highest for two years and the next highest for one year. In the event of a tie vote a new ballot shall be taken for the election of one or the nominees for the specific place for which such nominees are so tied. The nominee receiving the greater number of votes shall be declared elected for the specific place, and the other nominee shall be declared elected for the next lower place." Seconded and carried.

The Speaker The Secretary will please call the roll before we proceed to elections.

The Secretary called the roll and the following delegates responded

Arthur J. Bedell, Thomas W. Jenkins, James N. Vander Veer, Chauncey R. Bowen, J. Lewis Amster, Harry Aranow, Edward R. Cunniffe, William M. Dunning, Cornelius J. Egan, Edward C. Podvin, Frank M. Dyer, Joseph J. Kane, Myron E. Fisher, Raymond C. Almy, Edgar Bieber, George W. Cottis, Reeve B. Howland, Leo F. Schiff, John L. Edwards, Robert W. Andrew, William A. Krieger, E. R. Ritchie, Charles W. Bethune, John D. Bonnar, P. H. Hourigan, William W. Britt, George R. Critchlow, A. G. Bennett, Earl P. Lothrop, Sidney F. Blanchet, Clarence J. Whalen, Lyle B. Honevford, Norman L. Hawkins, Robert F. Barber, Elias H. Bartley, Thomas M. Brennan, William F. Campbell, Claude G. Crane, Roger Durham, Raymond Lauh, Charles H. Goodrich, Charles A. Gordon, Edwin A. Griffin, George D. Hamlin, Richard A. Henderson, O. Paul Humpstone, Frank D. Jennings, John E. Jennings, William A. Jewett, A. N. Thomson, J. Richard Kevin, Walter D. Ludlum, John J. Masterson, Harry H. Patrie, Thurston S. Welton, Harold A. Patterson, Nelson O. Brooks, Joseph P. Henry, Owen E. Jones, Floyd S. Winslow, Warren Wooden, Horace M. Hicks, Gustave A. Fensterer, George A. Newton, Theodore H. Allen, L. W. Zwisohn, Milton A. Bridges, Edward V. Collie, John Douglas, Robert H. Halsey, Harold Hays, William P. Healy, Ward B. Hoag, Henry Keller, Samuel J. Kopetzky, George W. Kosmak, Otto H. Leber, I. Milton Mabbott, Henry S. Patterson, William M. Patterson, James Pedersen, Abraham J. Rongy, Samuel J. Scadron, Frederic E. Sondern, DeWitt Stetten, Terry M. Townsend, Louis Tulipan, F. Leighton, Frederick J. Schnell, Robert L. Bartlett, Andrew Sloan, George M. Fisher, Albert G. Swift, T. P. Farmer, Homer J. Knickerbocker, Joseph B. Hulett, R. E. Brodie, Frank E. Fox, Carl Boettiger, Thomas C. Chalmers, Henry C. Courten, W. H. Jessup, J. R. Reuling, Ernest E. Smith, James H. Flynn, Peter L. Harvie, George Mord, Enrico C. Soldini, George A. Leitner, William B. Hanbridge, John R. MacElroy, Frederick C. Reed, Allen W. Holmes, Herbert B. Smith, Frank Overton, A. G. Terrell, Luzerne Coville, F. L. Eastman, J. Leonard Byrnes, Paul B. Fitzgerald, Francis R. Lyman, George B. Stanwin, Edward W. Weber, William R. Thomson, G. E. Stevenson.

The following officers and chairmen of standing committees were present

Nathan B. Van Etten, William H. Ross, E. Eliot Harris, George M. Fisher, Daniel S. Dougherty, James Pedersen, Howard G. Myers, Edward R. Cunniffe, Charles A. Gordon, Andrew MacFarlane, W. Warren Britt, Henry L. K. Shaw, John A. Card, Joseph S. Thomas, Nelson O. Brooks, William I. Dean, Harry R. Trick.

The following ex-presidents were present

Wendell C. Phillips, Grant C. Madill, James F. Rooney, Arthur W. Booth, Owen E. Jones.

The Speaker I will ask the Secretary to read the names of the two groups of tellers.

Dr Dougherty, Secretary

Number	one
John A. Card, Dutchess-Putnam, Thomas W. Jenkins, Albany, Luzerne Coville, Tompkins	
Number	two
George R. Critchlow, Erie, Ward B. Hoag, New York, William M. Dunning, Bronx.	

The Speaker declared the following officers and Chairmen of Committees elected unanimously: President, George M. Fisher, Utica; President-Elect, James S. Sadler, Poughkeepsie; Speaker, E. Eliot Harris, New York City; Vice-Speaker, Harry R. Trick, Buffalo; First Vice-President, John E. Jennings, Brooklyn; Second Vice-President, George M. Cady Nichols, Secretary, Daniel S. Dougherty, New York City; Assistant Secretary, Howard G. Myers, New York City; Treasurer, Charles G. Heyd, New York City; Assistant Treasurer, James Pedersen, New York City; Chairman of Committee on Scientific Work, Samuel J. Kopetzky, New York City; Chairman Committee on Public Health and Medical Education, Charles A. Gordon, Brooklyn.

any member or agent thereof shall be paid to the Treasurer of the Society. The Board of Trustees shall approve the bond of the Treasurer as to amount, form and surety, it shall employ a public accountant to audit the accounts of the Treasurer and Secretary and other agents of the Society and present a statement of the same in its annual report to the House of Delegates. The Chairman of the Board of Trustees shall make a report to the House of Delegates of its transactions for the year and of the amount of money belonging to the Society under its control."

I move the adoption of Section 35. Seconded.

The Speaker Are you ready for the question? All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 36 "Three members of the Board of Trustees shall constitute a quorum."

I move the adoption of that. Seconded.

The Speaker All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 37 The following shall be the order of business at meetings of the Board of Trustees

One Calling the meeting to order

Two Roll call by the Secretary

Three Reading of minutes

Four Communications

Five Reports

Six Unfinished business

Seven New Business

I move its adoption. Seconded.

The Speaker All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida In Section 37 after the word "council" insert "Board of Trustees." I move its adoption. Seconded.

The Speaker All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida The fourth line from the bottom Section 37, for the word "council" substitute "Board of Trustees." Seconded.

The Speaker All those in favor of that modification say aye, opposed, no. Carried unanimously.

Dr Sloan Section 23 Strike out the words shall have charge of all properties and the financial affairs of the Society and which means that the duties are transferred from the Council to the Board of Trustees. Seconded. Carried.

Dr Sloan Section 39 For "Council or Executive Committee" substitute "Board of Trustees," fourth line. Seconded.

The Speaker All those in favor of that say aye, opposed, no. Carried.

Dr Sloan Section 39 Seventh line. Change the word "president" to "Chairman of the Board of Trustees." Seconded.

The Speaker All those in favor of that change say aye, opposed, no. Carried unanimously.

Seventh line from the bottom, change the word Council to Board of Trustees. Seconded and carried.

The Treasurer shall be a trustee of the Merritt H. Cash Fund, the Lucien Howe Fund, and such other special funds as may be established" is stricken out because all those funds are provided for in the custody of the Board of Trustees instead. Seconded.

The Speaker All those in favor of that say aye, opposed, no. Carried unanimously.

"The treasurer shall make an annual report to the House of Delegates and then in addition to the Board of Trustees whenever requested"—that is added. Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

The Speaker "The salary of the treasurer," it says, "shall be fixed by the Council." The word "Council" is to be stricken out and "The Board of Trustees" inserted. Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 42 The second sentence strike out "the members of the Council" and insert "the members of the Board of Trustees." Seconded.

The Speaker This provides that trustees be allowed railroad fares for attending the meetings. All those in favor say aye, opposed, no. Carried unanimously.

Section 42 provides that proper vouchers must be filed with the secretary and approved by the Executive Committee. "The Executive Committee" is stricken out and "The Board of Trustees" inserted. Seconded.

All those in favor say aye, opposed, no. Carried.

Section 42 states "the vouchers of such expense shall be approved by the Executive Committee." Strike out "Executive Committee" and insert "trustees." Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Section 42 reads "provided a proper statement of such expense shall have been presented to the secretary and approved by the Executive Committee." Strike out "Executive Committee" and insert "trustees." Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Section 42 provides "This time may be extended for any cause by the Council or Executive Committee." "Council or Executive Committee" is stricken out and "Board of Trustees" inserted. Seconded.

All those in favor say aye, opposed, no. Carried unanimously.

Dr Sloan, Oneida Section 66 After the "House of Delegates, Council" insert "Board of Trustees." Insert "Board of Trustees" after the word "Council." Seconded.

The Speaker These are the notices for the annual meeting. All those in favor of that say aye, opposed, no. Carried unanimously.

Instead of ten days' notice in order to have these all covered by the same blanket article, the House of Delegates and the Council and the Board of Trustees are all to be allowed seven days' notice instead of ten. Seconded.

All those in favor of that say aye, opposed, no. Carried unanimously.

BOARD OF CENSORS

The Speaker Article VI reads "The President, the Secretary, and the eight district councillors shall be known as the Board of Censors. The House shall elect them annually." It is moved to strike out the words "The House of Delegates shall elect them annually." Seconded.

The Speaker All those in favor of the adoption of that amendment say aye, those opposed, no. Carried unanimously.

Section 17 says the censors shall be nominated as provided in Article 6 of the Constitution and elected by a majority vote without debate. That should be stricken out. Seconded.

Those in favor of striking that out (Section 17) say aye, opposed, no. Carried unanimously.

The Speaker Strike out censors, third line, Section 14. Carried unanimously.

DELEGATE TAKES OFFICE

The Speaker Dr. Wightman introduced last year an amendment to the by-laws which is reported in the proceedings of the House of Delegates, that the term of a delegate of a county Medical Society shall begin at the first annual meeting of the House of Delegates subsequent to his election. Dr. Wightman's amendment shall be added at the end of section 19 as follows "The term of a delegate elected by a County Medical Society shall begin at the first annual meeting of the House of Delegates subsequent to his election." Now, Dr. Wightman was appointed a committee of one to think over this amendment and present it or a substitute. He has

Dr Keen, Kings I move as a substitute that the whole question be referred to the Council. Seconded. Upon a rising vote the Secretary announced forty-nine for the motion, nineteen against.

The Speaker The motion to refer it to the Council has been carried and it is so ordered.

Dr Halsey, New York I move that the rest of the report that was not referred to the Council be adopted. Seconded and carried.

PLACE OF MEETING.

Dr Schnell, Niagara I rise to present an invitation from the Medical Society of the County of Niagara to the Medical Society of the State of New York to hold the next meeting at Niagara Falls in 1927. I also take pleasure in presenting invitations from the Mayor of the City of Niagara and the President of the Niagara Falls Chamber of Commerce.

Dr Bedell moved that the whole question be referred to the Council with power to act. Seconded and carried.

RETIRED MEMBERSHIP

Dr Dougherty, New York, Secretary I move the election of the following to retired membership, they having qualified and the certificates of their County Societies having been properly presented:

"Lucius C. Andrews, Pitcher, Ernest R. Birkins, New York City, Michael Erlwein, New York City, Orlando I. Hallenbeck, Canandaigua, Philetus A. Hays, Afton, Thomas Urquhart Joyce, Brooklyn, Robert F. Macfarlane, Astoria, Emil Mayer, New York City, Benjamin Morje, New York City, George W. Sargent, Seneca Castle, Homer Erastus Smith, New York City, Richard G. Wiener, New York City." Seconded and carried.

PRESIDENT'S GREETINGS

It was moved and seconded that the House of Delegates hear from the newly elected President, Dr. George M. Fisher.

Dr Fisher I want to assure you that through the

coming year it is going to be my endeavor to give a good share of my time to the State Medical Society. I want to be among you. I want to find what you want and I want you to know what we want, and I trust that should any errors be made you will consider them errors of the head and not of the heart. I thank you.

VOTE OF THANKS.

Dr Bedell, Albany I move a vote of thanks to our hosts for supplying this excellent meeting place where I have not been suffocated by vile cigarettes and where everything about it has been made comfortable, and in going around the hotel I know that the meeting places are going to be very satisfactory. I, therefore, move you on behalf of the House of Delegates a vote of thanks to our hosts and to the Committee on Arrangements especially. Seconded and carried unanimously.

Dr Bedell, Albany I move a vote of thanks to the tellers.

Seconded and carried.

SPECIAL COMMITTEE ON COMPENSATION LAW

Dr Critchlow, Buffalo I move that the Special Committee appointed by Dr. Van Etten or a similar one be continued for another year to further study the question of the Compensation Law and report to the next House of Delegates. Seconded.

The Speaker It is necessary to suspend the By-Law on Reference Committees in order that you may act on it right away.

It was moved, seconded and carried by a two-thirds vote.

The Speaker Now you are considering the motion of Dr. Critchlow. Is there any discussion?

All those in favor will say aye, opposed, no. Carried.

Dr Bedell, Albany I move we adjourn. Seconded and carried.

The House of Delegates thereupon adjourned.

E. ELIOT HARRIS, *Speaker*

DANIEL S. DOUGHERTY, *Secretary*

Chairman Committee on Legislation, Henry L. K. Shaw, Albany, Chairman Committee on Arrangements, referred to the Council, Chairman of the Committee on Medical Economics, William Warren Britt Tonawanda.

The Speaker The Speaker in his address also made the following recommendation in regard to the election of delegates to the American Medical Association.

The By-laws of the American Medical Association provide that every third year there shall be a re-apportionment of the delegates in proportion to the membership of the constituent associations as recorded in the office of the A M A secretary on April 1, of the year in which the apportionment is made. The New York State membership on April 1, 1925, was 10,396 and on the basis of one delegate to each 750 members or fraction thereof, New York will be entitled to 14 delegates to serve in the next House of Delegates of the American Medical Association.

Section 18 of the New York State By-laws provides that the delegates of the American Medical Association shall be elected in accordance with the Constitution and By-laws of the American Medical Association. Section 2 of the By-laws of the American Medical Association states

"Delegates and Alternates from constituent associations shall be elected for two years. Constituent associations entitled to more than one representative shall elect them so that one-half as near as may be, shall be elected each year."

In order to conform to the By-laws of both the American Medical Association and the State Society, I make the following recommendation

"Nominations shall be made for not less than double the number of delegates to be elected. There are ten delegates to be elected and at least twenty names should be placed in nomination."

"The ballots voted shall not contain more than ten names for delegates. In the order of the highest number of votes cast the first seven shall be declared elected as delegates for two years, the next three shall be declared as elected as delegates for one year, the next seven as alternates for two years, and the next two as alternates for one year."

So that you elect ten delegates and nine alternates, because Dr. Wende, who was a delegate to the A M A has died but his alternate is still living

I submit that for your adoption

Dr. Phillips, New York I move its adoption

Seconded and carried

The following trustees were nominated and declared duly elected

William H. Ross, Brentwood, for five years, Grant Madill, Ogdensburg, for four years, Nathan B. Van Etten, for three years, Arthur W. Booth, Elmira, for two years, and Frederick H. Flaherty, Syracuse, for one year

The following delegates to the American Medical Association were elected for two years

E. Eliot Harris, New York City, Daniel S. Dougherty, New York City, James N. Vander Veer, Albany, Nathan B. Van Etten, New York City, Richard Kevin, Brooklyn, George A. Leitner, Piermont, and Orrin Sage Wightman, New York City

The following were elected delegates to the American Medical Association for one year

Arthur J. Bedell, Albany, Arthur G. Bennett, Buffalo, Thomas C. Chalmers, Forest Hills

The following were elected as alternates to the American Medical Association for two years

Arthur S. Chittenden, Binghamton, Thomas H. Farrell, Utica, George B. Stanwix, Yonkers, William D. Johnson, Batavia, Nelson O. Brooks, Oneida, Terry M. Townsend, New York City, Joseph B. Hulett, Middletown.

The following were elected alternates to the American Medical Association for one year

Frederick H. Flaherty, Syracuse, and Henry S. Paterson, New York City

AMENDMENTS TO CONSTITUTION AND BY-LAWS, CONTINUED

The Speaker The Chairman of the Committee on By-laws will continue his report.

Dr. Sloan, Oneida Section twenty is to be modified. It reads "The Council shall meet at the close of the annual meeting of the Society," and a number of the members of the Council would like to go away before that. An amendment was put in last year, stating the Council shall meet at the close of the Annual Meeting of the House of Delegates instead of at the close of the Annual Meeting of the Society. It will now read "The Council shall meet at the close of the annual meeting of the House of Delegates to organize for the ensuing year and shall continue in office until their successors are elected and qualified." Seconded and carried

The Speaker After the "chairmen of the Standing Committee" add "and the Editor-in-Chief of the State Journal" Seconded and carried

Now, there is an amendment placed last year that requires your action, namely, by adding after the "past presidents" the words "secretaries who shall be life members with voice but without vote." All those in favor of putting in past secretaries as members of the House of Delegates will say aye, those who are opposed, no. Carried

Dr. Sloan, Oneida Your Committee offers the following resolution "Resolved that the Executive Committee is empowered to make verbal changes in any paragraphs which do not alter the sense and to re-letter paragraphs and re-number articles and sections of the Constitution and By-laws"

I move its adoption

The Speaker The object of that resolution is to authorize the Executive Committee, where insertions have been made and new lettering is required, to re-letter, and also where new sections require re-numbering, that they may re-number them, also if there are any verbal changes required to make good English, without altering the sense, that they may have the privilege to improve the English—without altering the sense of any paragraph

That is before you for adoption. Seconded and carried

Dr. Kopetsky, New York I move the adoption of the Constitution and By-laws as a whole as amended

Seconded and carried

PROPOSED AMENDMENTS TO BY-LAWS

Section 42 Dr. Sloan I move that the By-Laws, Section 42, be amended as to \$100 being insufficient for the district branches. See Report Reference Committee on Council and Councillors page 463

Dr. Sloan I move that the By-Laws, Section 18, be amended to read as follows

Delegates to the American Medical Association shall be elected in the calendar year preceding the meeting of the House of Delegates to which they are elected and in accordance with the Constitution and By-Laws of that body

The Speaker As these are proposed amendments to the By-Laws, they will be placed on file with the Secretary

ACCEPTING EDUCATIONAL FUNDS FROM OUTSIDE SOURCES
Dr. Halsey, New York Reference Committee on reports of Committee on Public Health and Medical Education

"The Committee recommends the Board of Trustees consider the request of the Committee on Public Health and Medical Education to accept from outside sources such funds as it may deem proper for the furtherance of the work of the Committee." (Pages 427 and 463)

Dr. Bedell, Albany I move as an amendment to the committee's report, that the whole question of financing this proposition be carried on through the County Society in which the problem is presented. Seconded.

THE COUNTY MEDICAL SOCIETY IN PUBLIC HEALTH

While a movement is undergoing evolution and development, its growth and progress are not readily apparent to those immediately engaged in the work. It is impossible to form a judgment of the activities of ten thousand physicians, scattered in sixty county medical societies, unless the facts are carefully collected and analyzed, and then are compared with similar activities in past years.

The intentional deliberate practice of public health and civic medicine by physicians generally is a development of the last half decade. The science of public health became possible about two decades ago when discoveries in bacteriology rendered preventive medicine possible on a large scale. Then came a decade when departments of health developed practical methods in the art of the practice of public health, and then came a period of teaching the thousand or more health officers of New York State the modern methods of public health practice.

The departments of health of New York State and of its larger cities completed the standards of the new practice a decade ago, and then came the next step—that of bringing the standards to the knowledge of physicians generally. The work was comparable to that of teaching the physicians the standards of surgical asepsis in the decades of the eighties and nineties, and it has been done with greater facility than that of securing the practice of surgical cleanliness.

The physicians of New York State have taken a definite stand in regard to the practice of public health and civic medicine. Those who are engaged in its practice realize the immaturity of the work, but on the other hand, it is a great item of progress that a definite start has been made, and that the great army of physicians have marched ten per cent along the hundred per cent road that ends in perfect practice of the new fields of practice.

The great forward step that has been accomplished by the physicians of New York State has been the recognition of the County Medical Society as the essential agent in the practice of public health. It was formerly the custom to say "The medical profession stands for the prevention of disease", and then to leave the initiative of the practice of preventive medicine to individual physicians, while there was no one authorized to speak in the name of the medical profession. In the new development the medical societies of the counties and the State take formal action in adopting the newer standards of practice and in urging their members to act in accordance with them. There is a mutual recognition of one another by the Departments of Health and the medical societies. The depart-

ments of health are recognized as the authoritative sources of knowledge of proper procedures and power of their enforcement, and the physicians are the recognized agents in applying the procedures in actual practice to the people.

There is also a third party involved—the people themselves. They are represented by the lay organizations engaged in public health. The standard state-wide public health organization is the State Charities Aid Association, and a branch organization in each county is analogous to the county medical societies.

New York State has thus a trinity of public health organizations, all modeled on the same line. Historically, their development has been first, the State Department of Health and a local department in each city, village, and town—some 1,200 in all. (A county health department will be the next logical step in the evolution of the official public health organizations.)

Second, the lay organization develop county health committees for the purpose of combating that typical disease, tuberculosis. Their success in that field have led naturally to the extension of their work to other fields of disease prevention—to diphtheria by means of the campaign for the acceptance of toxin-antitoxin, and to the diseases of adult life by means of the periodic health examination.

Third, the State Medical Society has inspired the county medical societies to adopt the broad preventive programs which have been developed by medical leaders, standardized by other medical men in departments of health, and popularized by the lay organizations.

The birth of these ideals one after another has been slow and tedious, and attended by many mishaps and radical operations. They have weathered the usual run of children's diseases and have survived an appalling mortality in still births and defectives, but they are now lusty youths of which their triple parents are proud.

The final delivery of the newborn united trinity of public health organizations in New York State was accomplished quietly and unostentatiously, and was announced in a few modest sentences at the annual meeting of the Medical Society of the State of New York, through the formal report of Dr. C. A. Gordon, Chairman of the Committee on Public Health and Medical Education, and the after dinner speech of Mr. Homer Folks, Secretary of the State Charities Aid Association. After the lusty child has taken its first long steps and, like the infant Hercules, has strangled a few disease monsters, the story of its conception and birth will doubtless form a tale as thrilling as that of the birth of the idea of asepsis.

MINUTES OF THE ANNUAL MEETING

A description of the Annual Meeting of the Medical Society of the State of New York appears in two issues of this JOURNAL. A general, unofficial report was printed in the issue of April 15th, and an official report of the proceedings appears in this number. The reports of the officers and committees are printed in this number with the minutes of the House of Delegates for convenience of reference. The printed reports and minutes are in constant use by the officers

and the Council, and the Executive Committee, and every member of a county society will wish to know what his delegates did at the annual meeting.

The proceedings of the annual meetings show an increasing range of activities of the State Society, some of which were unknown a few years ago. The growth in administration and medicine has kept pace with that along scientific lines.

THE COUNTY MEDICAL SOCIETY IN PUBLIC HEALTH

While a movement is undergoing evolution and development, its growth and progress are not readily apparent to those immediately engaged in the work. It is impossible to form a judgment of the activities of ten thousand physicians, scattered in sixty county medical societies, unless the facts are carefully collected and analyzed, and then are compared with similar activities in past years.

The intentional deliberate practice of public health and civic medicine by physicians generally is a development of the last half decade. The science of public health became possible about two decades ago when discoveries in bacteriology rendered preventive medicine possible on a large scale. Then came a decade when departments of health developed practical methods in the art of the practice of public health, and then came a period of teaching the thousand or more health officers of New York State the modern methods of public health practice.

The departments of health of New York State and of its larger cities completed the standards of the new practice a decade ago, and then came the next step—that of bringing the standards to the knowledge of physicians generally. The work was comparable to that of teaching the physicians the standards of surgical asepsis in the decades of the eighties and nineties, and it has been done with greater facility than that of securing the practice of surgical cleanliness.

The physicians of New York State have taken a definite stand in regard to the practice of public health and civic medicine. Those who are engaged in its practice realize the immaturity of the work, but on the other hand, it is a great item of progress that a definite start has been made, and that the great army of physicians have marched ten per cent along the hundred per cent road that ends in perfect practice of the new fields of practice.

The great forward step that has been accomplished by the physicians of New York State has been the recognition of the County Medical Society as the essential agent in the practice of public health. It was formerly the custom to say "The medical profession stands for the prevention of disease", and then to leave the initiative of the practice of preventive medicine to individual physicians, while there was no one authorized to speak in the name of the medical profession. In the new development the medical societies of the counties and the State take formal action in adopting the newer standards of practice and in urging their members to act in accordance with them. There is a mutual recognition of one another by the Departments of Health and the medical societies. The depart-

ments of health are recognized as the authoritative sources of knowledge of proper procedures and power of their enforcement, and the physicians are the recognized agents in applying the procedures in actual practice to the people.

There is also a third party involved—the people themselves. They are represented by the lay organizations engaged in public health. The standard state-wide public health organization is the State Charities Aid Association, and a branch organization in each county is analogous to the county medical societies.

New York State has thus a trinity of public health organizations, all modeled on the same line. Historically, their development has been first, the State Department of Health and a local department in each city, village, and town—some 1,200 in all. (A county health department will be the next logical step in the evolution of the official public health organizations.)

Second, the lay organization develop county health committees for the purpose of combating that typical disease, tuberculosis. Their success in that field have led naturally to the extension of their work to other fields of disease prevention—to diphtheria by means of the campaign for the acceptance of toxin-antitoxin, and to the diseases of adult life by means of the periodic health examination.

Third, the State Medical Society has inspired the county medical societies to adopt the broad preventive programs which have been developed by medical leaders, standardized by other medical men in departments of health, and popularized by the lay organizations.

The birth of these ideals one after another has been slow and tedious, and attended by many mishaps and radical operations. They have weathered the usual run of children's diseases, and have survived an appalling mortality in still births and defectives, but they are now lusty youths of which their triple parents are proud.

The final delivery of the newborn united trinity of public health organizations in New York State was accomplished quietly and unostentatiously, and was announced in a few modest sentences at the annual meeting of the Medical Society of the State of New York, through the formal report of Dr. C. A. Gordon, Chairman of the Committee on Public Health and Medical Education, and the after dinner speech of Mr. Homer Folks, Secretary of the State Charities Aid Association. After the lusty child has taken its first long steps and, like the infant Hercules, has strangled a few disease monsters, the story of its conception and birth will doubtless form a tale as thrilling as that of the birth of the idea of asepsis.

GRADUATE MEDICAL INSTRUCTION

The courses of instruction that are made available to county medical societies are not designed to make specialists out of general practitioners. They are designed to teach a few methods which specialists have found of essential use in dealing with disease conditions. The successful teachers have chosen a few methods which have stood the test of time and experience and have taught them, to the exclusion of that which is controversial or unproved.

A great difference between a specialist and a general practitioner is that the specialist is constantly trying new experiments and recording his findings, while the family doctor confines himself to the proved standards. Every case of disease is accompanied by signs which are pathognomic, and by others which are only confirmatory or accessory, or accidental. It is the business of the specialist to take note of those signs—their frequency and extent, and their presence and absence in other diseases.

It is also the business of the specialist to interpret those signs, and to separate those which indicate a harmless anatomical condition from those which indicate active disease.

When a wise specialist gives a demonstration to a class of general practitioners, he will not discuss every possible sign and symptom, but

will emphasize a few which point to a particular disease. This may be illustrated by the subject of pulmonary tuberculosis. Consolidation, exudation, cavitation, fibrosis, and enlargement of glands may produce an array of signs which require two pages of text for their mere enumeration. But the signs on which an expert clinician depends are surprisingly few, and a knowledge of them may be readily imparted to a class of physicians. If these few signs are well learned and the methods of eliciting them are acquired, the physician will be able to diagnose practically all his cases of incipient tuberculosis. Yet after a teacher has demonstrated the essential signs it frequently happens that some one gets up and discusses a number of other signs to the great confusion of the students. The point is not whether or not these signs are present, or whether or not they are valuable—the point is that if one sign is of great value in nearly every case, there is no need of burdening the doctor's mind with unnecessary facts.

The secret of the success of the demonstrations made under the auspices of the Committee on Public Health and Medical Education has been that the teachers have emphasized the points which are of essential value in diagnosis and treatment.

THE AMERICAN MEDICAL ASSOCIATION MEETING

The Annual Meeting of the American Medical Association was held in the City of Dallas, Texas, from April 19th to the 23rd inclusive. It was a wonderful demonstration of the interest taken by medical men throughout the union in things pertaining to the scientific advance in medicine.

The City offered ample accommodation to the five thousand odd physicians who were in attendance. More could not have been done to make the delegates comfortable and the City of Dallas is to be thanked for its cordial hospitality to every visiting physician. The Meeting was noted for an unusual smoothness of procedure. The scientific sessions were held at the Fair Grounds under very fortunate conditions.

As Dallas likes to be called a City of the south-west the meeting was attended by a large group of medical men from this part of the country, men who would ordinarily not have the opportunity of being present at a great medical meeting unless it was near home. They came by the score, proud of their State, proud of their profession and presenting a clean cut type of doctor, well worthy of the profession.

Dr McReynolds as President of the Dallas County Society, accepted the responsibility of

host and left no stone unturned in the entertainment of his guests. There were receptions, golf tournaments, concerts, luncheons and dinners. The social phase met its climax in the barbecue held in honor of the visiting physicians. The difficulty of following the procedure of any meeting where the business is referred to committees, is in securing the amended report as formally adopted by the Association. These reports in due time will be in print and can be read by all who are interested as they will be printed in the JOURNAL.

A visit to the Scientific Exhibit brought home more strongly than ever the close relationship which exists between the manufacturer of instruments, of drugs, the publication of books and many other things necessary to the medical profession.

Much painstaking care was shown by all exhibitors to anyone who seemed interested. It was more than a duty, it amounted to a privilege to stand in a booth from nine until five, answering the questions of an interested moving audience.

The sections in the side halls were crowded, amplifiers from the platforms intensified the voice of the speakers so there was no difficulty in be-

ing heard In noting the amount of work necessary to prepare section rooms, we were reminded of the admonition of Dr Olin West, Secretary of the A M A, when a meeting place for the Annual Session was under discussion He stated that many cities, while most hospitable in relation to entertaining a guest, did not realize the immense amount of time necessary to secure a proper place for scientific and section meetings There is an endless amount of detail to secure dark rooms, lantern facilities, loud speakers, moving picture facilities, etc, and in spite of the fact that the local authorities assume this responsibility the fact is the parent organization has to see it is properly done It takes a big thriving city to handle the situation, one which has not only hospitality but facilities

New York State was particularly interested in the resolution offered by one of its members and passed by the house of delegates, congratulating Governor Smith on his published platform with regard to the medical profession and the request that he see fit to sign the Medical Practice Act Bill, recently passed by the Legislature

Dr Phillips as new President of the Association was very well received His address was constructive and showed a sincerity of purpose which should materially contribute to the advance of medicine during his administration

Dr Matthias Nicoll, Jr, Commissioner of Health of the State of New York, as Chairman of the Committee on Public Health, very ably presented the relationship which exists between the physician and those engaged in public health activities

There was nothing of a startling character brought out at the meeting which has not already been reviewed in the literature The impressive feature was the immensity of medicine in all its forms and the fact that we are dealing with a public commodity when we handle the health of the people This can be no private prerogative on the part of the physician, as he is only one agent in the prevention and treatment of disease and should be willing to co-operate in any way which would mean better health and longer life to the community

The meeting in Dallas was a great success

LOOKING BACKWARD—THIS JOURNAL TWENTY-FIVE YEARS AGO

This JOURNAL for May, 1901, contains a letter from Dr Francis M O'Gorman referring to the alleged demonstration of the parasitic origin of cancer It says

"Situated in the City of Buffalo is the State Laboratory for the investigation of the cause of carcinoma For three years or more this work has been carried on under the direction of Dr Harvey R. Gaylord, and from time to time he has informed the medical profession that the cause of cancer would be stated positively and definitely in a short space of time. The profession waited patiently for the day when a demonstration and proof of the true cause was to be made. Eagerly did we accept the invitation sent out to the effect that we were to be told the cause of the dread disease. The profession assembled in the Alumni Hall of the Medical Department of the University of Buffalo and listened with great joy and pride to what Dr Gaylord told them. He stated that he was now in a position to positively

prove by correlating the observations of other investigators, that the cause of cancer is a parasite. Congratulations were extended on all sides for being so fortunate as to live in such a wonderful age, and, more so, to be among the men to whom this great discovery was first announced"

Dr Gorman then goes on to doubt the reliability of discovery He also calls attention to the claim of another doctor, announced in the morning paper, that he had demonstrated the parasitic three years previously and that as the result of his discovery, he has been able to treat cancer successfully, as is believed and corroborated by both the laity and reputable physicians

In this year of our Lord, 1926, we still hear of the discovery of cancer parasites and of the exploitation of cures by advertising physicians

MEDICAL PROGRESS

Fasting as a Cause or a Cure of Convulsions

—Hugh Josephs, writing in the *American Journal of Disease of Children*, February, 1926 (xxxi, 2), suggests that short fasting periods may be a cause of convulsions in children, especially that type of convulsion which is seen at the onset of acute infections. He points to the frequency with which convulsions occur in the early morning in children who have recurring attacks of eclampsia. In studying several cases in which recurrent convulsions occurred with the onset of infectious disease, hypoglycemia was found to be an accompaniment although the blood sugar concentration was not excessively reduced. Acetone bodies have been found early in the attack in the cases studied, but their diagnostic significance is not very great. Vomiting took place in a number of the cases and in some it overshadowed the convulsions to such an extent that the cases were classified as "recurrent vomiting." There seems to be much evidence accumulating that recurrent vomiting in many cases is dependent upon hypoglycemia. It would appear probable, then, that attacks of recurrent vomiting and the convulsions described in this paper are both manifestations of the same condition. The therapeutic test—rapid recovery after the administration of glucose—is useful only when the child has shown no tendency to spontaneous recovery, as in one of the cases cited. As spontaneous recovery is the rule, the therapeutic test has a very limited application. The author proposes a test—the estimation of the fall in blood sugar concentration during a sixteen-hour fast—which he thinks may prove to be of value.

This eclamptogenic action of fasting does not appear to be apprehended by P. Karger, who has an article in the *Klunische Wochenschrift* of March 19, 1926, in which he strongly advocates abstention from food as a therapeutic measure in cases of repeated seizures threatening status epilepticus in children. The fast, the author says, will be of benefit, even if not curative, in the majority of cases, but it should not be prolonged beyond one week. What is the mechanism, he asks, whereby this benefit is obtained? Is it the mere abstention from food? May it not be inanition acidosis which confers the improvement? The author has incidentally tested every conceivable diet with a view to associating it with fasting. A regimen of meat, eggs, and cream naturally favors the development of acidosis and despite the fact that in general flesh foods are held to be harmful to epileptics the author has seen benefit from a

brief use of the diet in question which may be used for a few days after a fast. As for any diet securing acidosis without the fast, that seems impossible. After fasting-acidosis has appeared it is easy to get the acetone out of the urine by having the patient drink slightly sweetened water or tea, but with its disappearance the seizures grow worse. It appears that not every one can benefit by the acidosis diet and we cannot tell in advance who will be helped. The author has tried the fat-free diet without any benefit and this is true also of a non-protein diet and a salt-free diet. The bulk and consistency of the food should be kept down, a fact known for generations to epileptologists, but here it is a question rather of quantity than of composition of food. Too much and too indigestible food certainly has a bad influence over the number of seizures.

Treatment of Puerperal Eclampsia—

Howard F. Kane (*Surgery, Gynecology and Obstetrics*, April, 1926, xlii, 4) discusses the etiological theories of eclampsia which have had the strongest support, namely infection, glandular dysfunction, incompatibility between fetal and maternal blood, fetal toxins, and diet and faulty elimination, and makes a plea for conservative treatment. In treating eclampsia all possible causes should be borne in mind and efforts should be directed toward combating them. The influence of diet and faulty elimination has practically been proved by the clinical results of treatment directed toward the correction of errors in this particular. At the Freedmen's Hospital, Washington, D. C., the attempt has been made to employ every method which seems to have value. Believing that the convulsion in itself is a source of grave danger, an attempt is made to control it by the use of morphine, $\frac{1}{2}$ gr. with the first convulsion and $\frac{1}{4}$ gr. with each succeeding convulsion until the respirations fall to 10 per minute. No anesthetic is used. After the patient is narcotized elimination is effected by stomach lavage until the return is clear, and then by colonic irrigations of 5 gallons of 5 per cent sodium bicarbonate solution. After the lavage 2 ounces of magnesium sulphate is introduced through the tube. The irrigation is not repeated, as one flushing seems to clear the bowels. If the blood pressure is above 170 mm. venesection is performed, 600 to 1,000 c.c. being withdrawn, or less if the blood pressure falls to 150 mm. This measure the author regards as of the greatest importance. After venesection, 10 per cent glucose solution intravenously to the amount of

500 c.c. is administered in the hope of thereby aiding the regeneration of damaged liver tissue. Acidosis is combated by retention enemata of 6 ounces of glucose and soda solution, 5 per cent each, every four hours. Profuse sweating is not induced and veratrum viride is not used. Unless the second stage of labor is very rapid, delivery is hastened, after full dilatation of the cervix, by forceps or version. Cesarean section is reserved for the primipara with an undilated cervix in the occasional case which does not improve under conservative treatment. In the author's series of 18 cases, 10 were treated conservatively without a death, 3 cases in which cesarean section was performed soon after admission terminated fatally. All cesareanized eclamptics, however, do not die, and many eclamptics will die in spite of all treatment.

Cerebral Affections Following Vaccination—Professor Carl Leiner of Vienna discusses the cases of encephalitis and meningitis which have been reported in the past few years as developing from 9 to 15 days after vaccination. There is nothing in the older history of this resource to point in this direction. Vaccinia is chiefly a local reaction although exceptionally this becomes general—so-called generalized vaccinia. In any kind of generalized infection there may be an intracranial complication, although in general vaccinia nothing of this sort has hitherto been reported so far as the author's search through the literature gives evidence. It is stated only that the local reaction in these cases is usually pronounced. In 1923 Lucksch saw personally three cases and knew of four more, and of the seven children five died; he obtained two autopsies and was able to show beyond doubt that death had been due to encephalitis. Then Bastiaanse of The Hague collected notes of 34 similar cases which had occurred in the whole of Holland during 18 months of 1924-25 with a mortality of over 40 per cent—deadlier if anything than ordinary epidemic encephalitis. In addition several cases of serious meningitis have been reported. The author has seen three cases of encephalitis in Austria and reports that not only the encephalon but the cord and peripheral nerves may be involved, so that the affection may be spoken of broadly as a meningoencephalomyelitis with polynenritis. Fortunately his patients all recovered. There are two possibilities in regard to causation—one of indirect causation in which vaccination may be supposed to activate the exciting cause of epidemic or herpetic (laboratory) encephalitis, and the other of direct causation in which the exciting organism of vaccinia directly attacks the brain. What must be done to prevent the serious complication? We must not vaccinate any child with a cutaneous lesion or with tuberculosis, etc., lest we cause too severe a reaction

and, further, the strength of the lymph should be reduced from 1 10-1 20 to 1 100-1 200. Strong reactions are not desired.—*Medizinische Klinik*, March 19, 1926.

Neurolapine and the Alleged Vaccination Encephalitis—W. F. Winkler, chief of the University Hygienic Clinic of Rostock, refers to certain so-called "cultures" of vaccine produced *in vivo* by inoculation of various tissues, including the nervous. According to his nomenclature dermovaccine results from ordinary vaccination, and neurovaccine is produced by brain inoculation, the animal of choice for the latter being the rabbit, Levaditi of Paris, who first made these cultures, termed them neurolapines from *lapin*, rabbit. This work of Levaditi dates back to 1921. Quite recently isolated cases of cerebral symptoms, suggesting encephalitis, following vaccination have been reported from Holland, Czechoslovakia, and Germany, and from Switzerland there have been reported two cases of serous meningitis. This is something quite new in the annals of vaccination and the few cases reported, in view of their extremely small evidence must be regarded as calling for careful investigation. Variola and vaccinia have not been known to be neurotropic hitherto, although Levaditi, after his production of neurolapine, wondered whether nervous tissue did not show a slight predisposition to react to the virus. It is possible, as shown by the spread in recent years of lethargic encephalitis, that the central nervous system of civilized man is beginning to show lack of resistance to certain viruses to which it was once immune. The modern appearance of metasyphilis and of poliomyelitis points in this direction. It may be that vaccination must act in concert with some unknown casual factor in order to elicit brain symptoms, therefore until we know more of this new complication it is well to be circumspect in the vaccination of children who suggest any vague infectious process, as shown by the general condition. The author has made many original investigations with these vaccine types preparing dermovaccines and neurovaccines from rabbits and vaccinating human beings as well as rabbits *in vivo*, but has been unable to see any evidence of neurotropism in the general reaction. Neurovaccine produces typical vaccine pustules, also some abortive forms.—*Deutsche medizinische Wochenschrift*, March 19, 1926.

Relationship Between the So-called Herpes Virus and the Virus of Variola—B. Heymann gives an interesting account of a rediscovery by modern laboratory men of a fact well known to Jenner. Recently, thanks to the research of a number of workers, much has been learned on the experimental side of the properties of the serum of herpetic vesicles in causing laboratory disease

in animals This principle, from its contagiousness, seems to be responsible for cutaneous disease of a certain type among the poor and crowded It has also been noted that when these children are vaccinated there is a certain antagonism between this principle and vaccine virus, for the latter takes in an atypical manner The two show much parallelism in animal experiments, but thus far one serum will not immunize an animal against the other, so that any question of identity should not come up It is of much interest to note that Jenner was thoroughly familiar with the fact that children with herpetic eruptions gave trouble to vaccinators of the period, and he contributed a long article on the subject in an epistolary form to the *London Medical and Physical Journal* in 1804 It is not easy to divine just what Jenner meant by herpes, but study of contemporary dermatologists, notably Willan, who also was very familiar with the Jenner phenomenon, shows that any eruption in the form of clusters of small vesicles was so understood, whatever might be its intimate nature If the crops of vesicles were recent more interference resulted than if they were old, for with the latter vaccination often took properly Jenner points out that the same inhibiting effect was seen in the practice of variolation or direct inoculation of patients with smallpox virus After several years all knowledge along this line seems to have died out until the recent discoveries of Doerr, Levaditi, and others—*Deutsche medizinische Wochenschrift*, March 12, 1926

Infectious Muscular Erosion—Few cases have been recorded in which infections have caused herniation of the large bowel through muscular erosion A case described by Mast Wolfson, with a discussion of the X-ray findings by Lloyd Bryan (*Boston Medical and Surgical Journal*, April 1, 1926, xciv, 13), occurred in a woman, aged 38, whose chief complaint was pain in the right lower quadrant and in the right leg She entered the hospital in May, 1920, and remained for three months, during which time she ran a low grade septic temperature As she had had a cesarean section seven years previously, and a month before several gynecological operations, and physical and x-ray examinations were negative, the diagnosis was post-operative adhesions and hysteria Several months later, the patient was again sent to hospital and this time was dismissed with the diagnosis of neurasthenia Then followed a long history of recurrent abscess in the lower lumbar muscles, under the iliac crest The contents of these abscesses showed at different times nonhemolytic streptococci, Gram-negative diplococci, colon bacilli, and finally tubercle bacilli The x-ray examinations during this period were negative At length, in May, 1925, a large mass, 9 cm in diam-

eter, was found over the iliac crest The mass was soft, fluctuant, and there were no signs of muscle guarding over the area Slight pressure caused the mass to disappear, and on release of pressure it immediately returned Roentgen examination, with an opaque meal and injection showed the descending colon and the sigmoid to be displaced slightly to the right, and the ascending colon and cecum extending through the lumbar muscles posteriorly into a large hernial sac At operation, through an incision over the right iliac crest, no muscles could be demonstrated until the sac of the hernia was dissected free of the adjoining tissues down to the hernial opening, which was directly over the right iliac crest and was about 4 inches in diameter, this also revealed the remains of an old perforated retrocecal appendix, at least 8 inches in length, much injected, and with an abscess about the size of a walnut at its tip After removal of the appendix and closure of the hernial opening, the patient made an uneventful recovery The case shows what sequelæ may result from an undiagnosed appendical abscess

Regulation of the Salt Intake in Therapeutics—H Finkelstein, writing in the *Munchener medizinische Wochenschrift* of March 12, 1926, discusses the possibility of increasing the resistance of the tissues to microorganisms through diet and the alternate plan of making the soil unfavorable for the growth of the germs, and adds that the younger the patient the more such possibilities are in evidence At first sight it would appear that the two plans are mutually opposed, for while the first suggests a hypernutrition the second equally suggests restriction of the diet This would seem to make it difficult or impossible to combine the two plans in the same subject In this connection we first think of Czerny's theory of the exudative diathesis in nursing infants, for Czerny long ago showed that these infants become worse on a nutritive diet, one rich in milk, and improve strikingly on a milk-free and salt-free diet These infants are overweight and show water retention and a kind of water-logging of the skin and subcutaneous, mucous, and submucous tissues, due to lymph stasis They are predisposed to hypersecretion and exudative processes Just how far milk is injurious from its salt content alone does not appear, but this is regarded as an important factor over and above any others On the so-called dry treatment these infants improve strikingly The same principle appears to hold good for older children and adults who present symptoms suggestive of the exudative diathesis, and the salt-poor diet should always be tried here The opposite conditions prevail in the tuberculous child despite the fact that one with the lymphatic diathesis is very susceptible

to the attack of the tubercle bacillus Here the patient should receive an excess of salt, for his condition is one of water elimination and salt will promote retention At the same time there should be a minimum of sugar and sugar formers for these are believed to encourage the proliferation of organisms in the tissues

Nature of Trachoma—Krumbach of the ophthalmic clinic of the University of Munich sums up an extensive digest of the more recent studies of trachoma in part as follows The epithelial inclusions are not peculiar to trachoma nor to the conjunctiva and have no significance, not even diagnostic The consensus of opinion among the great majority of writers is that certain factors are requisite for the occurrence and endemicity of the affection—first a specific exciter of which we know only that it belongs to the filtrable and ultraviolet viruses, it can transmit the disease in 24 hours by contact, as in kissing and the use of handkerchiefs or towels in common and through the agency of flies Second, a certain peculiarity of the lymphoid or adenoid tissue of the mucous membrane of the eye which may be dependent on a third factor, that of a community in which hygiene and sanitation are defective and in which there are mostly individuals of a lymphatic or asthenic habitus Such communities form natural breeding places of trachoma This doctrine, while containing nothing intrinsically improbable, is in harmony with all of the known clinical facts—*Klinische Wochenschrift*, January 22, 1926

Treatment of Epithelioma of the Skin—De Rezende comments on the absence of any mention of caustics in the successful treatment of epithelioma in the standard dermatological work of Sequeira, the London authority, who discusses only the knife, roentgen rays, and radium in this connection This omission may be excusable in city practice, especially in the large cities of the world where there is every convenience for hospitalizing and treating patients by the methods above stated, but the author who practises in a small city in the State of Sao Paulo, Brazil, found it advisable to utilize the old method of chemical caustics Beginning in 1915 he was able to make a very favorable report three years later in the *Brazil-Medico* The application recommended in place of an arsenical or caustic potash or other caustic paste was a complicated mixture containing arsenous acid, sulphate of copper methylene blue, methyl violet, quinine hydrochloride, and tartar emetic with other substances evidently intended to diminish the pain—camphor, menthol, phenol, and antipyrine While

the results were good there were numerous disadvantages so that the author revised his formula by omitting the methylene blue and methyl violet and adding chloral hydrate, while at the same time he made use of basilicon ointment as an excipient He has had no occasion to modify the formula further The latter is composed of 10 gms of the ointment with 1 gm each of antipyrine, crystalline phenol, camphor, chloral hydrate, and menthol, 0.25 gm each of arsenous acid and sulphate of copper, 0.50 gm tartar emetic and 0.75 gm quinine This ointment causes an intense inflammatory reaction followed by free suppuration To produce this effect it is not necessary that the lesion be ulcerated The ointment is applied repeatedly when necessary in order to produce the reaction The author has many photographs which illustrate the success of his method—*Brazil-Medico*, February 20, 1926

Bulbocapnine in the Treatment of Tremor—Dejong, of Amsterdam, demonstrated that the tremor of paralysis agitans can be controlled by the use of bulbocapnine, and he also found that by the administration of large doses of this drug a syndrome simulating catatonia could be produced These experiments have been repeated and confirmed by Hugo Mella (*Archives of Neurology and Psychiatry*, March, 1926, xv, 3) If bulbocapnine (one of the alkaloids of *Corydalis cava*) is given to a cat in doses of 40 mg per kilogram of body weight, the cat goes into a typical "fixed posture" within about ten minutes It may be set up on its haunches with its forepaws against a support and will remain in that position for several hours Voluntary motion ceases The animal can be bent like a piece of lead pipe If the dose be increased above 40 mg per kilogram of body weight, tonic and clonic convulsions follow, and death ensues With the ordinary dose, the animal recovers its normal motor activities within from twelve to eighteen hours, and shows no after-effects In an elderly man with paralysis agitans, twenty-four minutes after the injection of 200 mg of bulbocapnine no tremor was registered on a kymograph The effect lasts from three to six hours then it is necessary to repeat the dose The drug has been given by mouth, but requires a little more time to take effect The experimental work on animals seems to indicate that bulbocapnine may be of value in the study of catatonia Some preparations being combined with other alkaloids, are toxic and should not be used in the doses mentioned

NEWS NOTES

LEGAL OPINION REGARDING CHIROPRACTORS INTRODUCTION

By REED B. DAWSON, Counsel,
Medical Society of the County of New York.

In the prosecution of irregular, unlicensed practitioners, especially chiropractors, the authorities entrusted with the enforcement of the Public Health Laws have been for some time seriously handicapped by a lack of uniformity of interpretation of provisions of the Medical Practice Act among the numerous magistrates before whom in the first instance, prosecutions have been brought. In order to secure a uniformity of ruling with respect to chiropractors and definitely to settle their legal status, District Attorney Banton of New York County, through his assistant, Michael A. Ford, in charge of enforcement of Public Health Laws, with the very efficient cooperation of Dr. Louis I. Harris, New York Commissioner of Health, and George V. McLaughlin, Police Commissioner of New York, secured evidence against 50 chiropractors openly "practicing" in

New York County. After these cases had been prepared, the entire situation was laid before Chief Magistrate William McAdoo, and the desirability of having all of these cases heard before him pointed out. The Chief Magistrate readily offered to hear the cases.

During the course of one of the hearings at which were present over 40 defendant chiropractors, their counsel and friends, the Chief Magistrate delivered the opinion which is set forth below. I have never had the pleasure of hearing or reading a finer or clearer exposition of the law on any point than that contained in the Chief Magistrate's opinion.

There is no chiropractic claim which is not dispelled in a manner so plain and convincing as to make them ridiculous.

THE OPINION OF MAGISTRATE McADOO

The law of this State is very careful to protect the public from irregular and unlicensed practitioners, in both the law and medicine. It recognizes that these two great professions, one dealing with the liberty of the person, the rights and responsibilities of citizens and the powers of Government, and the other which deals with individual and communal health, the prevention of disease, the cure of disorders, the prolongation of life against diseases, epidemic or endemic, should be carefully regulated as to those who practice, so that it may be free from the irregularities of unlicensed practitioners and the shysters and quacks who prostitute these professions.

In the law, it has guarded the profession by giving semi-judicial powers of inquiry to Bar Associations for disbarment where the facts will warrant it, so that the law is much better protected than medicine in respect to the licensed persons who practice that profession or who assume to do so without a license.

In an age of cults in a big city like this, we have large numbers of healers by the occult, healers by the mechanical, healers by the mysterious, healers of the mind and healers of the body, and the title "doctor" has become so common outside of those legally entitled to the appellation, that it is a matter of distinction not to be called one. Most of these cults had their origin long ago and died a natural and proper death. They have now been resurrected, disguised in new clothing, and put forth as fresh discoveries. Their sponsors say they are based on common

sense, which in this instance is scientific nonsense. With many of the sick there are no limits to their credulity and they grasp at anything that holds out the shadow of hope. The Medical Barnums follow the same rule as the showman, and with financial success.

Mysterious boxes containing electric power, and which electricians laugh at, patented, mechanical disease detectors, that in effectiveness are below the charms of the Indian Medicine Man and all this with literature and advertising and publicity in which stand out words about "systems," "discoveries," "mysteries" and "muscles" and finally about "dollars."

Altogether fifty defendants have been summoned before me for practicing medicine without a license under the Public Health Law, Article 8, Section 160, and those which follow. All of them proclaim themselves as Chiropractors and several of them have gone on the stand and described the methods used by them on patients who come to them for relief or cures for various ailments, disorders and diseases.

The evidence produced here against the defendants comes from women police officers acting under the Health Department. The evidence given by these officers is substantially the same in all of the cases. Slight variations as to the facts would not, in my opinion, alter the legal aspects as against any one of the defendants.

The officer went to the office of the Chiropractor, complained of various pains, aches, disorders and symptoms indicating disease or an ill condi-

tion of the body In some of the cases the Chiropractor accepted these symptoms as the diagnosis made by the patient herself and proceeded to give her the treatment which these people administer to all who come to them There was in some of the cases a variation in that the Chiropractor expressed opinions as to the causes of the patient's ailments, which, in my judgment, amounted to a diagnosis of the kind usually made by physicians

The treatment as testified to here is based on the idea that all bodily ailments and diseases are caused by lack of tonicity in the nervous system, or by impingements of the vertebrae at some points on the spinal cord, from which radiates nerves to different organs and parts of the body The treatment therefor is what they call "adjustment of the vertebrae" so that it shall be like a chain suspended in air, in which the links all meet evenly and are articulated regularly and properly This adjustment beginning at the neck proceeds the full length of the spine The adjustments have to be made frequently and there does not appear to be any permanent adjustment following one or more manipulations Some of the Chiropractors combine massage and something approaching Osteopathic practice with Chiropractic, and these apply themselves to the whole body, the circulatory as well as the nervous system

In many of the cases, if not in most of them, the patient was advised as to diet and the dietetic rules laid down were similar to those known to people in general in connection with certain diseased conditions of the body As diet is now considered by all regularly licensed physicians as most essential in the relief and cure of disease, I consider that giving the patient rules as to diet is really prescribing the same as physicians in general do, and as there is no professional diagnosis by learned and expert physicians, the patient's symptoms are followed as a rule with regard to diet

In the case of these policewomen, who are in good health and suffering from no bodily disease, and who gave false and simulated symptoms, the Chiropractor did not hesitate to advise long courses of treatment and a very rigid diet, which might or might not be injurious to a healthy person

The Chiropractor, in general, will not admit that diseases are caused by the inhalation or inoculation of germs into the body On the contrary they claim that if what they call the tonicity of the general nervous system is kept up, everybody would be immune to the leading diseases such as Typhoid Fever, Pneumonia Tuberculosis, Diphtheria and Malarial Fevers In this connection it is well to remember that the leading causes of death throughout the United States as to diseases, are Tuberculosis, Pneumonia, Heart and Vein diseases, Bright's Disease, Cancer and Diphtheria

As against the treatment of ailments and dis-

eases by these people we have to keep in mind that the laborious, patient, highly scientific and unselfish efforts of doctors have practically abolished Yellow Fever, not only on this Continent but throughout the World, and of course malarial diseases to the same extent, by demonstrating beyond doubt that these fevers come by inoculation by mosquitoes carrying the germs The same may be said about Typhoid Fever and Diphtheria, not to speak of the conquest of Cholera among animals This learned, expert, scientific profession hopes in the future to conquer both Cancer and Pneumonia and everyone knows what they have done in lowering the death rate in Tuberculosis

All this has been done as the science of medicine has advanced, not so much by the use of drugs, as was formerly the case, but by discovering the sources of the disease and meeting these life killers at their origin and destroying them

It is a matter of life and death with the patient whether he or she shall be treated by physicians thoroughly acquainted by long courses of study and actual observations and practice in the dissecting rooms and at the great hospital clinics, or venture the most precious possession, health and life itself into the hands of people, who call themselves Chiropractors or what not, and who may be entirely ignorant of anatomy, physiology, and materia medica, and who simply practice so that by the use of their fingers they can manipulate the vertebrae making the segments snap, which often conveys to the poor patient that some wonderful mechanical adjustment is being made which will cure all of his physical troubles, ailments and diseases

I am convinced that all of this is contrary to Article 8 of the Public Health Law and that these people whether they put it on their cards or literature are really holding themselves out for "doctor" in the common acceptance of that word as it is used among people in general

If I am ailing why do I go to a Chiropractor? I go there to get relief from physical ailment I go there to be cured of disease Why should I pay anyone a considerable sum of money if I am not suffering from pains, disorders and diseases, which I believe that person can cure or at least relieve Would I pay the Chiropractor if he or she told me in the beginning "I will not diagnose your ailments", "I do not know what they are, I have not the expert knowledge of a physician, it is against the law for me to tell you what I think I will accept any statement you make and I do not propose to cure you, I will only relieve you, it will be a temporary relief and you must come frequently to me and let me manipulate your spine" In view of such a statement, would I put myself under the charge of a Chiropractor and pay him or her money It amounts in other words to saying—"I am only relieving you temporarily by adjustment of your

vertebrae I am totally ignorant as to what ails you I am going on the theory that if I can get your vertebrae in line with the spinal cord and the other nerves, I will relieve you" I use this word "relieve" because all of the Chiropractors insist with emphasis that they do not propose to cure anything They avoid this word "cure" because it is in the Statute It is useless in this connection with this as a legal proposition to argue that Chiropractic, like Osteopathy and Massage, may be useful in the treatment of disease under the care and direction of a licensed and practising physician

One witness here said that the Doctor he consulted, a regular licensed physician, made a false diagnosis of his troubles for which he paid him and took a prescription Why, certainly there are men both in the medical and law professions who are a disgrace to it Some of them are ignorant Nearly all of them prostitute the profession to get all the money they can out of the dupe clients and patients The majority of both these professions try to rout these fellows out every chance they get We do it through the Bar Association here in New York, and even they, God knows, don't get as many as they should of the shysters who rob people and facilitate and increase crime by aiding criminals in illegal methods

Article 8, Section 160 of the Public Health Law defines the practice of medicine as follows

Subdivision 7—The practice of medicine is defined as follows A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain injury, deformity or physical condition, and who shall either offer or undertake, by any means or method to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition

It will be noted in reading this Section that what cannot be done legally is in the disjunctive, and therefore, we could read it like this

"Who holds himself out as being able to diagnose, who holds himself out as being able to treat, who holds himself out as being able to operate or prescribe for any human disease, who holds himself out as being able to treat pain, who holds himself out as being able to treat injury, who holds himself out as being able to treat deformity or physical condition, and who shall either offer or undertake by any means or method to do any of these things"

Under these conditions I find that all of the defendants, as far as I have examined the cases, are violating the provisions of this Act, even if they only manipulate the spine and adjust the vertebrae, to use their own terms, and they, accordingly, should be held for trial in the Court of Special Sessions

The evidence taken in these cases has been under Section 82 of the Inferior Criminal Courts Act, which reads as follows

Section 82—Summons a When a complaint, oral or written, is made to a magistrate and the magistrate believes that in the public interest he should inquire into and investigate the complaint so made, he may, in his discretion, issue a summons which shall be substantially in the following form (See printed form attached)

I have taken formal complaint in most of the cases and I will do so with regard to the remainder When a formal complaint is taken the defendant would be sent to the District Magistrates' Court where the offense was committed, unless Counsel will waive that If any of the defendants insist upon a formal examination and no agreement has heretofore been made with the Court as to waiving that, I will transfer the case to the District Court and arrange the hearings so that I can go there myself and hear them.

There are many leading cases and among them are the following, which are controlling

People against Allcutt, 117, App Div 546

People against Somme, 120, App Div 20

People against Mulford, 140, App Div 716

People against Ellis, 162, App Div 288

Now, I want this to go out to the people of New York This whole proceeding, what happened here this morning, is conclusive evidence that this law should be changed so as to remove all doubts as to the jurisdiction of this Court. Now, look at the farce of the law Here are 41 people charged with endangering the health, communal and individual, and I, as a Magistrate, the best I could do for them is to give them what amounts to a full trial and inquiry under the summons, an elaborate hearing with able lawyers, like Mr O'Rorke to conduct what amounts to a full trial, absolutely, and argument on the whole law, going to the basis of it, involving the safety of the community and its health and its life, and I have to sit here wasting the public's time and passing along this case from an inquiry to a formal examination, to a remote District Court, down to the Court of Special Sessions, where already they have begun making motions to take these cases before the Grand Jury, and where undoubtedly they will make the same motions when they get these down there—in a simple matter of law and fact that any sensible magistrate could decide in an hour There are the eccentricities of the law, and people wonder why the law doesn't work Look at it! Why doesn't the law work? You make a farce of the law, make a joke of the law—full of technicalities, until the layman outside says, "Do we get justice?" And the answer is, "No, we don't get justice" The law transfers and transfers and adjourns Any common sense layman would say "Why shouldn't Judge McAdoo try the case." These defendants have

plenty of law for an appeal up to the higher courts if I make any error. But here a great question of public health is going to go off into the air. I feel I have done my duty, hampered and tied as I am. The law of criminal procedure

has become a box of tricks, and the constitution instead of being the paladium for the rights of honest men has become an ark for crooks, and metaphysical subtleties, a synthetic substitute for justice.

APPROVAL OF PRACTICE OF MEDICINE ACT BY THE AMERICAN MEDICAL ASSOCIATION

The Delegates at the Annual Meeting of the American Medical Association were interested in the fate of the Practice of Medicine Act in New York State and unanimously passed the following resolution:

"The medical profession of the United States as represented in national convention at Dallas, Texas, congratulate the Governor of the State of New York, Hon. Alfred E. Smith, in his demand for higher standards of medical education and the protection of the health of the citizens of the Empire State, so well outlined in his legislative message on assuming office. We further pray that there may be no deviation from this course,

and ask that full consummation be realized by affixing his signature approving the Medical Practice Act recently passed by the Legislature of the State of New York."

At the suggestion of Dr. Orrin S. Wightman, Editor-in-Chief of the *NEW YORK STATE JOURNAL OF MEDICINE*, the following telegram was sent to Senator Webb and Assemblyman Loomis:

"Delegates of New York State assembled in national convention at Dallas, Texas, congratulate you for your efficient, also successful consummation in the passage of the Medical Practice Act."

THE GOVERNOR'S HEARING ON THE PRACTICE OF MEDICINE BILL

"Smith to sign bill clearing the State of quacks" is the announcement with which the *New York Herald-Tribune* of Thursday, May 13th, heads a column article describing the hearing on the Practice of Medicine Bill held by the Governor on the previous evening. The *New York Times* also carried the heading "Executive indicates that he will approve measure aimed to rid the State of Quacks." While the Governor did not actually say that he would sign the bill, and even told the attorney for the chiropractors to file a brief of his opposition, yet his attitude was entirely favorable toward the bill.

The hearing was held in the Executive Chambers. The room was filled and between 300 and 400 persons were present. Women predominated, and judging by their applause most of them favored the chiropractors.

Governor Smith said he would follow the usual procedure in hearings and would consider the opposition first. The case was opened by Judge Newton B. Vanderzee, Ex-Surrogate of Albany County, who represented the State Chiropractor Society. He asked that the bill be voted for the reason that it would exclude from business four thousand chiropractors who were treating one million people. Governor Smith asked him to point out anything in the law that would deprive the people of their right to take chiropractic treatment and said that if the Judge would show him such a provision, he would at once veto the bill.

The Judge replied by quoting the old part of the law in which the practice of medicine is de-

fined. The Governor called his attention to the fact that the section which he read was in the old law and not in the new one at all, and that whatever rights the chiropractors had at present remained untouched in the new law. Judge Vanderzee admitted that the chiropractors had no rights at present, but, on the contrary, were law-breakers and were doing illegal things. Governor Smith asked him to show him anything in the new bill that made the practice of chiropractic any more illegal than it is at present. The Judge was evidently confused and at loss for an answer, and then suddenly fainted and was taken from the room. He came back later, but took no further part in the proceedings, nor did any one else take up the thread of his argument.

The great argument of the chiropractic sympathizers was that the million patients of the cultists united in asking that the illegal practitioners be legalized. Governor Smith replied that he had received 6,000 chiropractic letters, all written in the same style and saying the same thing, indicating to him that they had not originated spontaneously with the writers, but had been instigated by the cultists and therefore would have little weight with him.

The argument was made that the bill had originated with the State Medical Society whose members were jealous of the chiropractors and wished to put them out of business from fear of their competition. Governor Smith replied that the originators of the bill were well-known to be two great Departments of the State Government, that of Education and Health, and that the leaders

in the Departments were actuated solely by public health motives

A representative of the Medical Alliance of New York City, and of the East Side Clinical Society, each of which had 300 members, opposed the bill on the ground that the rich doctors would evade the law of registration while the poor doctors would register because they could not afford to pay the fine for breaking the law. It was developed later that the two organizations for which the doctor claimed to speak were composed of practically the same individuals—one organization being a scientific body and the other a social club that met after the medical session.

Dr Lester Volk, a Brooklyn doctor who has been in the Assembly and Congress, brought up the matter of legality of license fees to be paid by the doctors for annual registration. The Governor replied that the principle of license fees had become firmly established in the State Government and that their legality was beyond dispute.

Dr Walter Ludlum, representing the Medical Society of the County of Kings, said that the doctors of Kings County wished to rid the state of quacks but they did not think that the proposed law would be effective for the following reasons:

1. Physio-therapy does not belong in the bill and would open their way for licensing of incompetent persons.

2. The waiver clause was too liberal in regard to the graduate of schools for which no standard was set. A "Course" might mean one single page of text.

3. There would be difficulty in finding doctors qualified by temperament, ability and finances to sit on the grievance committee without pay.

4. Annual registration would have little effect on the enforcement of the law.

Dr A J Hambrook, Chairman of the Legisla-

tive Committee of the County of Rensselaer, said that his County Society had met on the previous evening and voted to oppose the bill on the ground that it placed the additional duty of annual registration on already overburdened doctors. He also thought the Grievance Committee might exceed its powers and might use them to revoke license for trivial reasons.

Mrs E Daniel Lockwood, president of the Citizens League for Constitutional Freedom, said she represented five thousand members of the League which was only a week old and had been formed for the purpose of securing freedom of choice of medical advisors. She said she knew of many people who had been helped by chiropractors after physicians had given them up.

The opponents of the bill had occupied nearly two hours and all their major objections had been answered by the Governor himself.

Those in favor of the bill were introduced by Senator J Griswold Webb, of Dutchess County, who had sponsored the bill in the Senate. He said that the lobby against the bill had been unusually highly organized and unscrupulous.

The speakers in favor of the bill were Dr Wendel C Phillips, President of the American Medical Association, Dr Matthias Nicoll, Jr, State Commissioner of Health, Dr Louis I Harris, Commissioner of Health of New York City, Mr Homer Folks, Secretary of the State Charities Aid Association, Dr J Richard Kevin of Kings County, Past President of the State Medical Society, and Dr Augustus B Downing, Assistant Commissioner of Education, who will have charge of the enforcement of the law. The speakers were brief and confirmed the stand already taken by Governor Smith, who showed a remarkable grasp of the essential features of the bill and of its objects. The physicians of New York State are under deep obligations to the Governor for expressing their point of view.

THE DAILY PRESS

POPULAR SCIENCE

The latest discoveries in science have a popular appeal to the imagination as revealing the "wonders" of nature. They also have a practical appeal in the two lines of finance and of health. Great business houses, such as the General Electric and the Standard Oil Companies, maintain research laboratories which are primarily for business purposes, but their discoveries also bring untold benefits to the human race.

There are also laboratories endowed for research in the realms of pure science, with no thought of the immediate capitalization of their discoveries in finance or health. Medical laboratories connected with colleges and endowed foundations made deep researches into abstruse problems of bacteriology, comparative anatomy, and other fields, and record their observations for the benefit of workers who may wish to apply them in practical ways.

Applications of new scientific discoveries are often revealed almost by accident. The New York *Sun*, May 7th, has a popular article entitled "X-Ray Research on Interaction," which describes some of the research work done under the direction of Dr F K Reichmyer, Professor of Physics in the Cornell University, on the effects of radiant energy on matter. The article quotes the Professor as saying:

"The experiments thus have led to no practical results, and they were undertaken with no thought of their application in industry or elsewhere, except as they have a direct bearing on scientific theories.

"The problems we are studying, however, may have a practical effect upon the lives of future generations," he said. "For instance, if we knew absolutely what the effect of X-rays upon matter is, we might have somewhat more of a clue as to whether X-ray could cure cancer. We cannot anticipate the commercial or other problems of the future, but we can determine and formulate the laws of nature with the confident expectation that future generations will make use of these laws in solving their problems."

The possible applications of the researches at Cornell are compared with the practical uses of X-ray, which are largely medical. Dr Reichmyer says:

It is absolutely certain that if Roentgen had been interested in finding some way to assist surgeons in setting bones, he would never have been studying vacuum tubes and electricity. Yet out of his accidental discovery came this new tool of X-rays which has revolutionized certain phases of medical practice."

"Thus, the scientist never knows how close he may be to some mighty discovery. The laboratory experiments of today may suddenly divulge one of the great laws of Nature which heretofore had been hidden."

The New York *Tribune* of May 7th has an editorial on a new kind of sound waves which Professor R W Wood of Johns Hopkins University is studying, especially their effects in curing disease. The editorial describes briefly the air waves which produce sound—starting with a frequency of about 32 per second, and rising to 25,000 as the limit of the audibility of high pitched notes. But the scale of rapidity of vibrations continues with increasing frequency, and it is concerning these waves that the editorial says:

"These are the new super-sounds. Just as there are colors beyond the violet which the human eye cannot detect, so there are sounds so shrill that they do not register in the ear at all.

"Most of the work with these super-sounds has been done under water, for these sounds travel much better in water than they do in air. Sounds vibrating as rapidly as a million times a second have been produced, sent through water, and detected. Professor Wood's recent experiments have been carried out with vibrations of about 400,000 a second."

The reason for the editorial is evidently the limited use to which the waves have been put in the business world, and the mystic belief that they will be of great use in medicine. The editorial continues:

"Such waves have been used by both the American navy and by the French navy for underwater signalling and for measuring the depth of the ocean by means of echoes from the sea bottom. Otherwise they have had no practical applications until the recent experiments, still quite inconclusive, on their employment for medical purposes."

The action which the editorial writer ascribes to the super-sound waves is most beautiful in logic, but utterly unscientific. He says:

"The theory of the medical action of these waves is that they stimulate the circulation of the blood. It is well known that massage helps the circulation, and the exposure of super-sounds may be considered an extraordinarily rapid variety of massage. If a bath tub filled with water is set into supersonic (sic) vibration with Professor Wood's new waves, and if you dip your elbow into the vibrating water, you may consider that the joint will be pulled back and forth a trifle for each of the 400,000 times each second that the wave is vibrating."

The value of the editorial from the medical point of view is its optimism. The writer has faith in the physicians as he closes his editorial.

"Whether this procedure actually has remedial value or not, only repeated experiments by physicians will determine. In any event, it is probable that the new super-sound waves will find increasing uses somewhere. It is only recently that such waves have been produced easily and cheaply by special kinds of apparatus. And when any new physical agent becomes easy to produce and to manage, it usually is not long before science finds something worth while for it to do."

It is a good thing for the human race that people have confidence in their scientists, and reward the discoveries of the radio, the flying machine, and the X-ray instead of killing them for alleged conspiracies with Satan. It was unconceivable to the people a few hundred years ago that any one should use an extraordinary power for the benefit of his brethren rather than for their destruction, and so the people and the church, and the State repressed a knowledge of discoveries as threatening even the omnipotent Creator.

Today, the people have acquired the habit of believing any wild claim of alleged discoveries. Possibly their faith is over developed. Electricity, light, and other forms of vibrations have done the seemingly impossible—why should they not do still more impossible things? Keeley's violin vibrations of a generation ago have their counterpart in Abram Electronic theory today, and it will doubtless evolve into a resurrection of the old astrological belief in the influence of the distant stars which have been proved to bombard us with mysteriously potent waves through the ether.

But the people will also listen to doctors who go to the trouble to educate them. It does little good to denounce a theory as a fake. The people wish to believe in the universal beneficence of vibrations and electricity, and light, and other mysterious agents. Physicians may at least instruct the people regarding the great danger from the X-ray, the electric battery, and the ultra-violet light. People should know that anything which is potent for good is equally powerful for evil when used ignorantly.

MILK GRAFT IN NEW YORK CITY

Those who deplore the impossibility of enforcing the prohibition laws may find a parallel in the milk grafts in New York City. Bootleggers among milk dealers have developed a system of defying the laws and corrupting the inspectors which rival the methods of rum runners—and the public seems equally apathetic in

both instances. The graft seems to go on unchecked even while prosecutions are under way and confessions are made.

New York City has boasted of the purity of its milk supply, and rightly so. No suspicion is attached to the larger dealers whose names are household words, and whose plants are standards of cleanliness, efficiency, and completeness. But some of the smaller firms are not impelled with the high honesty of the large dealers, and detection of their frauds is extremely difficult. The standard of four per cent cream is as difficult to enforce as that of one-half per cent beer, and law officials have the same difficulties in both. There is a slight difference in favor of milk inspectors, for the courts seem to uphold them in the rights of entry, search, seizure, and immediate destruction of milk that is below grade, although the advocates of personal independence would have great difficulty in adjusting those procedures with their vehement denunciation of similar action regarding beer.

The New York *Sun* of May 7th records the action of the Board of Health in forbidding the sale of both skimmed milk and Grade C milk. The item says:

"The Board of Health regards the prohibition of the sale of skimmed milk and Grade C as two of the really big constructive steps taken in the move to safeguard the city's milk supply."

"There was a determined drive made on the part of some ice cream makers and bakers to prevent the adoption of the resolution against the sale of skimmed milk, which is used largely in baking and in ice cream."

"The Board, on advice of counsel, in anticipation of a constitutional question being raised, permitted the bringing into the city of skimmed milk in hermetically sealed containers of a capacity not to exceed one-half pint. This will make the commercial handling of the product impossible. A second provision in the new skimmed milk ordinance prohibits the possession of skimmed milk in any place where milk or cream is held or offered for sale. Its possession is held to be prima-facie evidence of an intent on the part of the possessor to adulterate milk."

Skimmed milk is a wholesome food product, and many persons have advocated its sale to the poor. However, like one-half per cent beer, its possession and sale have opened endless opportunities for graft, until the Board of Health has chosen the lesser of two evils and forbade its continuance in the market. Doubtless the bakers and others will ask, "Where are our personal liberties when we can't get either milk with one-half of one per cent cream, or beer with one-half of one per cent alcohol?"

BOOK REVIEWS

ATLAS OF DISEASES OF THE SKIN. By Prof G RIEHL of Vienna and Prof Leo V ZUMBUSCH of Munich, with Diagnostic and Therapeutic Notes by JOHN B LUDY, A.M., M.D., Col Med O.R.C., U S Army, Dermatologist, Lankenau and Methodist Hospitals, Philadelphia. Three parts. Part I, Infectious Diseases of the Skin, 69 colored illustrations, Part II, Inflammatory Diseases of the Skin, 65 colored illustrations, Part III, Atrophies, New Formations, Hypertrophies, 61 colored illustrations all taken from life. P Blakiston's Son & Co., Philadelphia, 1925

The material comprising this work has been prepared from the vast dermatological clinics of the authors, and are reproductions direct from life in colors, by a new process or Color Photo-engraving

Volume I covers the infectious diseases, parasitic diseases and those which clinically resemble them

Volume II contains the inflammatory diseases while Volume III takes in skin atrophies, new formations and hypertrophies

The American author, Dr Ludy has given the reader the advantage of his long training and expert knowledge in dermatology and the letter-press is most valuable, the diseases are clearly described, their diagnosis simplified and their treatment by the latest and best means fully explained. The colored plates are exceedingly excellent and well selected. This atlas forms a valuable addition to any professional library and a ready means of diagnosis for the general practitioner or specialist. It is quite the best thing of its kind in years

NATHAN T BEERS.

REPORTS OF THE ST ANDREW'S INSTITUTE FOR CLINICAL RESEARCH. St Andrew's Fife. Volume 2. Octavo of 190 pages, with illustrations. London, Humphrey Milford, New York, Oxford University Press, 1924. Cloth, \$3.00 (Oxford Medical Publications)

The second volume follows along the same principles of thoughtful and careful investigations, as did the wealth of material incorporated in the first volume. The nerve ending question as to the nature of symptoms, with their end results are dwelt upon, to the minutest detail. Sir James Mackenzie's studies embracing cellular and organic activity is included, enumerating their relation to symptoms in living pathology. Illustrative cases are reported of coronary disease and heart pain with an idea of learning definite prognostic information. Response to effort tests seemed to be overshadowed by the careful study of the patients' symptoms which were of greater moment in gauging prognosis.

A chapter is included, presenting the radiographic appearance of healthy infants' chests. The infants' ages range from six days to fifteen weeks. There is another chapter which gives very interesting conclusions on the experimental injections of Indian ink and carmine, and the lymphatic activities following absorption of foreign material and the tubercle bacillus. The articles are the product of observations and discussions of every member on the staff of the Institute, though individually written by one of its members.

A T MAYES

EVERYMAN'S INSURANCE A NECESSITY FOR HOME PROTECTION. By FRAZIER HOOD Ph.D., Litt.D., Professor Psychology, Davidson College. D Appleton and Co., New York, 1925. Price, \$1.50

This small volume is written for the buyer of insurance. It explains the elementary principles of insurance in all its different fields. After analyzing the various aspects of insurance such as the legal, social, economic

and mathematical, the author states that the true concept of insurance is "a device or society evolved through many centuries whereby economic losses are shared among a large number of individuals and the amount each must contribute to the common fund from which losses are to be made good is calculated to a mathematical nicety." Most of the space is devoted to the different forms of life insurance, but fire and marine, liability and compensation, theft and other forms of insurance are thoroughly covered.

L. S.

CHILD HYGIENE. By S JOSEPHINE BAKER, M.D., Dr P.H. Octavo of 534 pages. New York and London, Harper and Brothers, 1925. Cloth, \$5.00 (Harper's Public Health Series)

No one is better qualified to write a book of this character than Dr Baker, whose reputation is not only national but also international in her chosen field.

During her administration as head of the Bureau of Child Hygiene of the New York City Department of Health she not only acquired prestige but also a vast experience in this sphere of work.

In wealth of statistics, tables, and schemes of organization and all the phases of the administrative side of the Child Hygiene problem, it would seem that this volume is almost in a class by itself.

It is not so much a guide for the physician or the young mother but rather a work of greater scope which might be followed with great benefit by the public health official, the philanthropic organization, and by all concerned with the social service problems which are so weighty in hospital and civic circles.

It is, then, as a reference book that Dr Baker's production will find its chief use, and as such it must be accepted as an authoritative standard to be followed and quoted with full confidence.

WM HENRY DONNELLY

SIMPLIFYING MOTHERHOOD, Being a Handbook on the Care of the Baby During the First Year. By FRANK HOWARD RICHARDSON A.B., M.D., Brooklyn Regional Consultant Diseases Children, N Y State Department Health, Chief Nutrition Class, Brooklyn Hospital. Chapter on Breast Feeding. By ISAAC A ABT, M.D., Professor Diseases Children, Northwestern University Medical School, Chicago, Ill. Illustrated. G P Putnam's Sons, New York, 1925. Price, \$1.75

This small book is a strong plea for breast feeding to mothers as well as physicians.

In accordance with the author's conviction that nearly every mother can nurse her baby, this little volume carries to a successful conclusion all the practical experience at the command of its author to champion that conviction.

It discusses, in every day English, the whys and wherefores of breast nursing.

In this little book, in a very earnest and straight forward manner, it is the object to bring before the young mothers of the country the life saving value of breast nursing. Confusing statistics and other useless matter has been judiciously omitted.

This all important problem—"Infant feeding" is here being discussed fluently, interestingly and always practically. With the completion of its final chapter the reader can not fail to see the term "Infant feeding" spelled "Breast feeding", although exceptions should always be borne in mind.

In conclusion, the book is compact, instructive, all practical and deserves a place among other books on preventive medicine.

HARRY APPEL

TREATMENT OF KIDNEY DISEASES AND HIGH BLOOD PRESSURE. By FREDERICK M ALLEN, M D Part I Practical Manual for Physicians and Patients Octavo of 210 pages Morristown, N J, The Physiatrie Institute, 1925

The object of this book as stated in the preface, is to present the subject of renal vascular diseases in a simple form and parts of it are written with the idea that it may be placed in the hands of patients. The greater part of the book could only be understood by a physician.

Except for the influence of salt on hypertension, most of the ideas of the author are in accord with those generally held. Uraemia is believed to be the result, not of the specific toxicity of any one substance, but of the general low grade toxicity of all the retained nitrogenous substances.

Among the probable factors concerned in hypertension, two are given, in which the author believes, salt plays a large part. These are pressure of the surrounding tissues upon the capillaries as by fat or fluid turgor in invisible edema and swelling of the capillary endothelium due to intracellular edema. He says, "granting an infectious or toxic injury, it is noticeable that most of the further processes mentioned are such as might readily be caused by salt. Edema, turgor, contractions of cells and arteriolar spasm appear to the writer to be due in large measure, directly or indirectly to either the osmotic influence or chemical stimulation of sodium chloride."

In the treatment protein is allowed generally, to the extent of 30 to 80 grams daily depending upon the type of patient, attention being directed to presence of nitrogen retention. That a salt free diet for hypertension is the proper one, is the persistent contention of Allen. Directions are given for following his plan. He states that no one has experience upon which to base criticisms unless he can prove that the sodium chloride in the daily urine has been kept below 0.5 gram daily for a sufficient period of time. He states that he worked out this method independently and believed it new until a search of the literature revealed the observations of Ambard.

W E McCOLLUM

THE NERVOUS CHILD. By HECTOR CHARLES CAMERON M.A. MD, FRCP Third Edition, 12mo of 233 pages, with 8 illustrations London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$2.30 (Oxford Medical Publications)

This is a very excellent book, though the title hardly suggests the contents.

As the writer himself says in a preface, he could hardly call his book "The Nervousness of the Normal Child," but a suggestion of its contents might be conveyed by calling it "The Management of the Child to Avoid and Cure Nervousness" or "Training Parents to Train Their Children."

However, it is directed at parents who have, or wish to avoid having, what they would call a nervous child, and therefore the title probably serves well to reach its desired audience.

The writer is evidently a very sensible and experienced physician and guide for mothers. His manner of teaching and his very expressions in some cases remind us of what we should like to and perhaps do say ourselves. We are particularly impressed with his chapter where he describes one of the fundamental attributes of children as what he first calls a "love of power" and then modifies to describe as their enjoyment of occupying the center of the stage, this with reference to many things but particularly to their negativism and troubling their parents and nurses in refusal of food.

With great pleasure we have added the volume to our "Parents' Library"

W D L.

ULTRA-VIOLET RADIATION AND ACTINOTHERAPY. By ELEANOR H RUSSELL, M D, B S, Dunelm and W KERR RUSSELL, M D, B S, Dunelm Goyder Scholar University, Durham, 1914, late Surgeon, Special Military Surgical (Orthopaedic) Hospital, Newcastle, forewords by SIR OLIVER LODGE, F R S, D Sc, LL D and SYDNEY WALTON, C B E, M A, B Litt William Wood & Co New York and E & S Livingstone, Edinburgh, 1925 Price, \$3.50

A strictly down-to-the-minute account of the subject of ultra-violet radiation. It sets forth in a clear and interesting manner the latest as well as the earliest observations upon the relationship of light and health. Based as it is on an extensive clinical experience in a land of deficient sunlight, the work deals authoritatively with the conditions which are amenable to treatment by the means described. The technical detail and the exposition of the mechanical features necessary to an understanding of the subject are very clearly and accurately set forth. The work as a whole is to be highly recommended, and the information which it contains will be of great value to all who practice medicine.

JEROME WEISS

VITAL CAPACITY OF THE LUNGS. A Handbook for Clinicians and Others Interested in the Examination of the Heart and Lungs Both in Health and Disease. By J A MYERS M S, Ph D, M D Octavo of 140 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$3.25

In this volume of 140 pages this diagnostic test is thoroughly described. The first chapter deals with the history of the study of vital capacity, credit being given to Hutchinson, who in 1846 published the results of a scientific investigation of the vital capacity in man. The next chapter describes those factors other than disease which influence the normal vital capacity, such as physical training, occupation, sex, age, obesity and race and nationality. Other chapters deal with the influence of disease upon the vital capacity of the lungs, limitations and uses of the test, measurements and instruments used and normal standards. A full bibliography is appended.

The author states in the chapter on the influence of disease that patients with vital capacities 15% or more below the normal should be most carefully examined for disease conditions interfering with the function of the heart or lungs. "Conditions of no present clinical significance which may reduce the vital capacity are old pleural adhesions, deformities of the thorax and ossification of the costal cartilages. Conditions of present clinical significance which reduce the vital capacity are cardiac disease, hyperthyroidism, emphysema, asthma, pleurisy, pneumothorax, pulmonary abscess, new growths, pneumonia and pulmonary tuberculosis."

W E McCOLLUM

PARASITOLOGY FOR MEDICAL STUDENTS. By ALEX MILLS KENNEDY, M D (Glas.) Octavo of 142 pages with illustrations London Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$3.00 (Oxford Medical Publications)

This little manual of 140 pages is an excellent book for students and physicians who desire a practical knowledge of parasites without going into the detail in which the parasitologist delights. The author describes insects, tape-worms, flukes, round worms, protozoa, spirochetes and fungi, the morbid conditions they cause and outlines prevention and treatment. The text is illustrated with numerous photographs of actual specimens.

NEW YORK, N. Y.

JUNE 1, 1926

HAY FEVER AND ASTHMA

Report of results in treating one hundred and fifty cases with High Frequency Electricity at the General Electric Plant at Schenectady during the season of 1925

By WILLIAM G. LEWIS, M.D.
ALBANY, N. Y.

IN May, 1918, in a paper read before this Society entitled, "Some Points in Electro-Therapeutics," there were included the satisfactory results that the writer had obtained in treating Rose Cold and Hay Fever with High Frequency Electricity over a period of a number of years. This method of treatment for these conditions has been continued with continued excellent results, both as to individual cases and as to the proportion of cases benefited.

In May of last year, through the courtesy of Dr. D. Glenn Smith, head of the medical and surgical departments of the General Electric Company's plant at Schenectady, permission was granted me to treat, during their working hours, as many as possible of the employees who suffered each season from Hay Fever. I wanted to prove or disprove by extensive trials the efficacy of the treatment I had been using. I also wanted to determine whether the results would be better if treatments were instituted some weeks before onset, as had been my custom in the past, or if it would be as well to await the first symptoms before beginning treatment.

From every person with whom I came in contact at "the Works" during the two and a half months when I spent over half of my time at the G. E. plant, I received most kindly consideration and herewith gratefully make acknowledgment to Dr. Smith, to his staff and to the various department heads.

* * * * *

The symptom-complex known as Hay Fever—having often as one of its symptoms an asthmatic condition—and Bronchial Asthma, as dissociated from Hay Fever, are so closely related as to causation and, from the writer's point of view, as to treatment, that they may well be considered together. Sajous, some years ago, applied the term "hyperaesthetic rhinitis" to Rose

Cold and Hay Fever. If we amend this to read "hyperaesthetic mucous membrane sensitiveness," we may use it as a designation for all conditions of the air passages where irritation of one kind or another is caused by pollens or other air-borne matters, which would include Rose Cold, Hay Fever and Asthma.

The best way not to get sick is to keep well—the best way not to have Hay Fever or Asthma is to have a normal condition of the mucosa of the air passages, and to attain this end, normal secretion of the epithelium of this mucosa is essential. In a large proportion of cases of Hay Fever, with and without Asthma—and of Asthma with and without Hay Fever treated, we have been able to bring about a normal secretion of the epithelium and a consequent normal condition of the mucosa, with complete or partial relief of symptoms. The foregoing is true as to results achieved, the remainder of the statement is purely speculative, based on theory and the evidence of results, which, in view of our limited knowledge regarding the secretions of the body generally, seems justified.

The sympathetic nerve system, controlling the secretory epithelium of the body, is our point of attack. By producing hyperemia over the ganglia of this nerve system we cause it to function normally instead of abnormally, to the end that the condition of the mucous membrane of the air passages may be changed from a state of being sensitive to pollens and other air-borne matters, to a state of normal resistance to such matters, as are the mucous membranes of so many of us who do not suffer from these conditions.

Mackenzie says that "the neurotic factor is due to abnormal excitability of the sympathetic system." Experience extending over a period of more than twenty-four years in the use of high frequency electricity has proven, in all classes of cases, that after producing a hyperemia over the sympathetic nerve system a sense of quietude is

* Read before the Medical Society of the County of Albany, March 9, 1925.

experienced by the patient, and the soporific effects are so marked in those who had been sleeping little or poorly, that it has become my practice to use this therapeutic measure for sleeplessness—in the absence of pain—before resorting to drugs

The great depression that so often accompanies Hay Fever even in the mildest cases, where the worst symptom is sneezing or running from the nose, is out of all proportion to the seriousness of the case and can be explained only by reason of the sympathetetic involvement

Three prime causes are named by writers as responsible for Asthma, Hay Fever and Rose Cold

- A An organic disorder of the mucosa
- B General nervous debility
- C An external irritant

All three of these can be summed up into one cause—namely, a *functional* disorder of the mucosa due to abnormal functioning of the sympathetic. This disfunctioning of the sympathetic would account for the “general nervous debility”, also for the so-called “organic disorder of the mucosa”—and correcting this disfunctioning of the sympathetic, as we are able to do by this method, will remove these two causes and the heretofore causative pollens and other air-borne matters would no longer prove irritating

As early as 1833 Roch and Sanson, in their *Pathologie*, said in regard to Asthma “It is exaggerated and perhaps produced by anything that tends to increase the irritability of the nervous system”

Jones says in the *Lancet* (Feb 28, 1920) “Asthma is a respiratory symptom that occurs in bronchitis, heart disease, renal disease and alimentary disease—and also as a pure neurosis”

Osler says “All writers agree that there is, in a majority of cases of bronchial asthma, a strong neurotic element. Many regard it as a neurosis in which, according to one view, spasm of the bronchial muscles, according to others, turgescence of the mucosa, results from disturbed innervation, pneumogastric or vasomotor” And —“the so-called Hay Fever is an affection which has many resemblances to bronchial asthma, with which the attacks may alternate”

Butler says “Some regard Asthma as a pure neurosis—a spasm of the bronchial muscles—others as a neurotic hyperemia and swelling of the bronchial mucosa”

Caille says—and we are so using it here—“The term Asthma should be employed only in connection with bronchial asthma, which may be defined as a vasomotor turgescence of the bronchial mucosa, although the pathology of the disease is unsettled” And under treatment he says “The neurotic element in Asthma must not be overlooked”

In making the statement that disfunctioning of the sympathetic is the cause of Bronchial Asthma and Hay Fever, we are going a step further than

the above quoted writers, and in treating over the course of the sympathetic nerve and its ganglia, and by means of high frequency electricity producing hyperemia, in an effort to cause that system to function normally, we are approaching these conditions in a sane, logical manner. The results of such treatment justify the statement that, although we may not know the primary cause of the disfunctioning of the sympathetic, we have learned that treating over this area has brought definite benefit to a very large proportion of cases of Asthma and Hay Fever so treated

The apparatus employed by the writer consists of an eight-inch Rhumkorff coil—such as was used in the first X-Ray machines—in combination with condensers, solenoid, spark gap and interrupter, the latter preferably of the Wehnalt type. When using this combination with an alternating current a rectifier is essential. This combination is probably the oldest form of high-frequency-current-producing-apparatus for therapeutic uses extant, and to my mind, is still the best for surface application

I have made many modifications to my original apparatus and to others that I have had occasion to fit out and use. One has been to adjust the capacity of the condensers to the particular current used. Another, when using the alternating current—as we have here in Albany—has been to increase the size of the Noden valve and adjust the relation of the elements. And in the Wehnalt interrupter, to replace the porcelain tube with a tube of fused quartz. The porcelain tube must be replaced frequently—about every three months—because of the cupping of the end, due to the heat generated and the disruptive effects of the continuous spark on the porcelain, resulting in irregularity of the current. The tube of fused quartz, being unaffected by heat or acid or spark, retains its original size and shape and should last indefinitely

I have been using this type of apparatus for many years and long ago reached the conclusion that it required more care and attention than a sick baby. That I was not discouraged because of this was due to the fact that I have been able personally to make my own repairs, and to construct new parts to replace those that have become worn out. Some years ago I was asked by one of the firm from whom I had secured my first piece of apparatus as to who kept it in working order, adding that in New York, where he was located, it was their custom, about every three months, to send one of their staff to repair and rehabilitate apparatuses of this type that were being used in New York City. I am relating these details in an effort to show at least one reason why this type of apparatus has fallen into disfavor both with physicians and with those who make and market electro-therapeutic equipment

The high frequency apparatus in general use to-day is of the step-up-transformer type. We may dismiss as unworthy of our attention the small so-called "violet ray" machines. Their therapeutic usefulness is limited to the one operation of fulguration and of this, only the most superficial kind. Their efficacy as compared with a real high-frequency-producing-apparatus may be compared with the soporific effect of 1-500th grain of Morphia as compared to the effects of a dose of $\frac{1}{4}$ of a gram.

For some purposes—diathermy, auto-condensation, fulguration, and in the newer type, for operative procedures—the apparatus of the step-up-transformer type is the instrument of choice. I have used a great many makes of this type, but have still to find an apparatus of the step-up-transformer type that delivers a current that is suitable for repeated surface applications, for the reason that a dermatitis is invariably produced over the treated area. When necessary I have, with the type of apparatus I use, produced a hyperemia over a given area three times daily for periods of three and four days with no irritation of the skin, merely the desired hyperemia.

The present day popularity of diathermy, and the reverse of surface application of high frequency electricity is due, in my opinion, to the foregoing facts. The patient, as a rule, resents treatment with a vacuum electrode when energized by an apparatus of the step-up-transformer type of sufficient capacity to deliver a therapeutically active current. During the past twelve years or more I have reported various conditions that I have treated with good effect with high frequency electricity, but other operators have failed to get similar results and have, perhaps, thought that I had exaggerated the results. It is more than likely that those who treated cases similar to those that I had reported used apparatus of the step-up-transformer type and their patients would not tolerate enough of this current, or treatment, to bring about the desired results.

There is not, as far as I have been able to ascertain, any exact method of measuring and comparing, as to therapeutic effect, the currents generated by these two types of apparatuses; and no method by which they might be brought to a point where the local effects would be identical. An expert recently made the remark that even if the two apparatuses did measure-up the same, there might still be differences in the currents delivered that were beyond the capacity of their instruments to determine.

In treating Hay Fever and Asthma—as in all conditions—the patient's general health and elimination should be looked into. Due to the fact that all who seek employment at the G. E. works are submitted to a rigid physical examination before being engaged, our preliminary examination of those applying for treatment dis-

closed no organic lesions. The only condition found worthy of our attention were occasional cases of auto-intoxication.

At the hospital of the G. E. plant—Building 45—a room was assigned to me, and the services of a technical (electro-therapeutic) assistant and secretary were placed at my disposal. After a very few days both of these assistants became as much interested in the work as I was and did everything in their power to see that all was done in the matter of treating patients and of keeping records that could be done to add to the success of the work.

In the beginning we had one apparatus and were able to treat between thirty and thirty-five patients during the working day, but very soon we found that our facilities would not meet the demand and a second apparatus was installed, the assistant using one and I the other, and we were kept busy throughout the working day.

On July 6th, questionnaires were distributed in the various buildings of the Works, in which the following information was asked for:

For those who have suffered from Hay Fever

Fill out the following form and hand same to

Name . . . Age . . . Sex . . .
Single . . . Married . . . Widowed . . .
(Strike out those not applying to you)

Address . . .
Employed in Shop No . . .
Employment . . .

For how many years have you had Hay Fever?

On or about what date do you have the first symptom?

What is the first symptom?

What is your most prominent or annoying symptom?

Make an (x) before any of the following symptoms that you may have had in the past during your attack

() Sneezing () Cough () Itching of eyes
() Itching of ears () Asthma () Head-ache () Indigestion

Any other symptom or symptoms? If so, mention them

How much time did you lose, because of your Hay Fever in 1924? . . . In 1923? . . .
In 1922? . . .

To what extent, if at all, was your work (efficiency) affected by reason of your Hay Fever while you were at work?

() Not at all () Very little () Considerably () %

Do you ever have Asthma outside of the Hay Fever season?

What is the condition of your health in general?

When does your attack end? . . .

Many were returned to us, and on July 16th we began treating as many as possible, selecting those who had had Hay Fever for the greatest number of years and those who had mentioned Asthma as one of their symptoms. It was our custom to assign to each patient a definite time to report for treatment and I am glad to say that with few exceptions these appointments were kept. As time passed and the timid ones discovered that those who had come for treatment had been able to return to their jobs and had been "treated" and not "electrocuted"—and it was a source of great surprise to see how fearful were these workers at and around electricity at this, to them, a new form of electricity—applications for treatment poured in on us and soon after the beginning of the Hay Fever season—August 15th—we were besieged with applicants for treatment, who had seen or thought they saw improvement in the condition of their fellow sufferers who had been having treatments. Because of our limited facilities we were compelled to select for treatment only those cases that gave a history of, or exhibited, the most severe symptoms, and this meant that cases having Asthma as one of the symptoms were to be considered first.

There were many applications for treatment from sufferers from Rose Cold who had already passed through their attack as well as from many who had ordinary "colds" or thought they had Hay Fever. Treatment was not given in any case where there was not a definite history of Hay Fever in previous years.

Treatments were given, as a general rule, three times a week, every second day, Sundays not being considered. The exceptions were the cases that presented themselves after the onset, where the asthmatic condition was severe. These cases we treated daily until this condition was relieved, usually by the end of the first week.

Treatment consisted of producing, by means of high frequency electricity—and I must again repeat, generated by a proper apparatus—hyperemia along the mid back, from the nape of the neck to the coccyx, and extending from three to five inches laterally, according to the size (bulk) of the patient. And according to the toleration of the patient, we used either a vacuum or conductor-filled electrode, the latter producing a more intense hyperemia in a shorter time.

We started our work on July 16th and continued until October 1st, administering during that time 2,589 treatments to approximately 200 patients. The discrepancy between the above number and the total on which this report is based is due to the fact that some were treated for conditions other than Hay Fever.

On our busiest day—August 26th—we saw and treated 77 patients.

As complete a record as possible was kept, and I wish to make a report of 131 cases treated, who all received more than six treatments. Of the cases that received six or less treatments I shall make a supplementary report.

The record that I shall present is compiled from

- 1 The questionnaire
- 2 A record that was kept during the course of treatment—a short history, confirming the answers in the questionnaire, number of treatments given, and remarks
- 3 Letters from the patients and their relatives and friends, received in answer to the following letters, which were sent to every patient on October 1st

Hospital Building 45,
General Electric Company

October 1, 1925

My dear ———

Will you be good enough to tell me, using the other side of this paper for that purpose, how your Hay Fever was this year as compared with former years? If you will go into detail, mentioning each symptom and stating whether it was worse, better or the same as in previous years, it would aid me greatly in preparing my report of the work we have been doing here this season.

Also, will you give the enclosed to the person who has been with you most for the past few years and ask that person to write his or her opinion of your condition this past season as compared with former seasons?

Thanking you for this information, I am,

Very truly,
(Enclosure)

Please write on the other side of this sheet your opinion of the condition of M
your as to Hay Fever during the past season as compared with previous seasons.

This information from a source other than the patient will greatly aid us in preparing our records, and we thank you for supplying same.

Yours truly,

To the first letters sent out we received about sixty replies. Later a duplicate letter was sent to those who had not responded to the first and from this lot we received about fifty answers. Of these, 99 are included in this report, leaving 32 from whom we have not heard directly.

It was my custom to be at the Works every Monday, Wednesday and Friday from 9 until 4, on the other week-days my assistant treated as many cases as possible. Because of the fact that the plant closed at noon on Saturday, I

found it necessary to go there on Saturday mornings as well, so that all patients could get the three treatments a week. There were many of the patients whom I saw so seldom that it was impossible for me to form an estimate of their condition from the records, and in order correctly—or as nearly correctly as possible—to arrive at the condition of these 32 patients who had not responded to our letters, my two assistants of last summer came to my office recently and together we went over the cards and questionnaires of these cases. I can conscientiously say that, if any errors have been made, they have been on the side of conservativeness.

The following table will show the results in the 131 cases treated, viz

25 were improved from 90 to 100%
33 were improved from 70 to 80%
28 were improved from 50 to 60%
27 were improved from 25 to 40%
6 were improved under 25%
12 showed no improvement.

For the purpose of determining whether it were better to begin treatment a month prior to the usual onset—as has been my custom—or at a later time—or to wait until after the onset, I have divided the cases into three groups, according to the time when treatment was begun, as indicated in the accompanying chart

CHART OF 131 CASES OF HAY FEVER TREATED AT THE G. E. PLANT, SCHENECTADY 1925

% of Improvement	90 to 100	70 to 80	50 to 60	25 to 40	Under 25	No Imp	Totals
Group A Treatment begun between July 16 and 31	15	13	6	13	2	5	54
% of Improvement	27.4	5	11	24	33.5	9.1	5
Group B Treatment begun between August 1 and 31	3	8	6	8		5	30
% of Improvement	10	26.3	5	20	26.2	3	16
Group C Treatment begun after August 15	7	12	16	6	4	2	47
% of Improvement	15	25.1	2	34	12.3	4	51.2
TOTAL	25	33	28	27	6	12	131
% of Improvement of all cases treated	19	25	21.1	3	20.2	3	41.2

It is possible that our total of cases is not large enough to draw final conclusions on this point, but from this number of cases we see that the greatest number of high percentage improvement occurs in Group A, where treatment was begun between July 16th and 31st, although this same group shows a larger per-

centage of non-improved cases than Group C, where treatment was begun after the onset. We shall, however, continue to advise the beginning of treatment on or about July 15th, until a record of a much greater number of cases is available and proves that instituting treatment at a later date is as advisable or more desirable.

Of the foregoing 131 cases, 49 reported Asthma as one of their symptoms. Of these, 47 showed marked improvement, 2, no improvement at all, as follows

15 were improved from 90 to 100%
12 were improved from 70 to 80%
8 were improved from 50 to 60%
12 were improved from 25 to 40%
2 showed no improvement.

CHART OF 49 CASES OF HAY FEVER HAVING ASTHMA AS ONE OF THE SYMPTOMS

% of Improvement	90 to 100	70 to 80	50 to 60	25 to 40	Under 25	No Imp	Totals
Cases with Asthma as a symptom	15	12	8	12		2	49
% of Improvement	30.3	4	24.1	2	16.1	4	24.1
Asthma cases, showing Group and % of Imp							
Group A	10	3	3	7		1	24
Group B	1	7	3	3		1	15
Group C	4	2	2	2			10

Cases of Bronchial Asthma without Hay Fever have responded to this form of treatment in about the same proportion as have the cases cited in this record, where the Asthma was one of the symptoms of Hay Fever. Repeatedly in Asthma with and without Hay Fever, having examined a patient immediately before giving a treatment and having found rales throughout the chest, I have found after a single treatment a very marked lessening of the chest sounds, with great relief to the patient.

Of the cases treated that have not been included in the groups reported because of insufficient number of treatments there are about twenty, seven have reported a better condition this year than in previous years, as follows

Two who had three treatments each, were 90% better

Three, who had respectively 2, 3 and 4 treatments were 50% better

Two, who had respectively 3 and 4 treatments were 25% better

Seven reported "no improvement", one had had 4 treatments, one had had 5 treatments and five had had 6 treatments each

Of these seven, one discontinued because our room was too draughty. One reported "no improvement", but his sister wrote that she had

noted a betterment in his condition after each treatment. Another told us on his last visit to us that he was better, his letter, however, said that he had shown no improvement, but he added that he "caught a cold" just after his last treatment. Half a dozen more cases were treated a few times each, of which we have no record beyond the fact of their having been treated.

Realizing the scepticism that is likely to be shown towards a form of treatment that, excepting in the hands of the writer, is new and untried, I have brought with me, for your inspection, the "documents in the case." I have, in three volumes, arranged according to the percentage of improvement, the questionnaires, the cards that were used as our records, and all let-

ters that were received from the patients and their relatives and friends.

CONCLUSIONS

Of all the cases of Hay Fever and Asthma treated, 91% showed satisfactory improvement.

Of the cases reporting Asthma as one of the symptoms, 95% were markedly improved.

From our experience of the past we shall expect the cases that were benefited last season to be as well or better during the coming and subsequent years, and that a large proportion of those who were not benefited will show some improvement during the coming season.

That results have justified our previous estimate of the efficacy of High Frequency Electricity in the treatment of Hay Fever and Asthma.

PAINFUL DISABILITIES OF THE FORE FOOT (METATARSALGIA)

By DONALD E. McKENNA, M.D., F.A.C.S.
BROOKLYN

METATARSALGIA is an inclusive term applied to a bizarre group of conditions which give pain in the fore foot. Anatomically it applies to affection of the metatarsals, phalanges and their contiguous soft parts. This is a broad interpretation of the term, but unless so considered, clinical confusion and diagnostic error ensues. The diagnosis of static metatarsalgia should be arrived at by a process of exclusion—which, in turn, necessitates an acquaintance with all of the possibilities pertinent to fore foot pain.

This paper has for its purpose the grouping of these possibilities, together with an enumeration of the distinctive features relative to each. Classification is most readily accomplished by the division of the affections into—(1) a local or focal group and (2) a general or systemic group. In the local group have been included

- 1—Hammer toe
- 2—Overlapping fifth toe
- 3—Morton's toe.
- 4—Ring-worm
- 5—Chilblain or pernio
- 6—Hallux rigidus
- 7—Hallux valgus
- 8—Fractured sesamoid bones
- 9—Papillomata
- 10—Deutschlander's disease
- 11—Juvenile deforming metatarsophalangeal osteo chondritis
- 12—Fracture of the metatarsals
- 13—Claw foot

- 14—Arthritic metatarsalgia (a) infectious, and (b) toxic
- 15—Static metatarsalgia.

The following represent the general conditions

- 1—Raynaud's disease.
- 2—Thrombo angitis obliterans
- 3—Erythromelalgia—Wier Mitchell's disease
- 4—Arterio sclerosis
- 5—Diabetes
- 6—Gout
- 7—Mal-perforant Perforating ulcer
- 8—Tuberculous osteitis
- 9—Syphilitic periostitis

We are not so intimately concerned with this latter, the systemic group—just a few remarks pertinent to the essential characteristics will be sufficient to identify each.

Raynaud's Disease is an affection of the blood vessels, occurring most frequently in emotional or neurotic women between the ages of 18 and 30. Both feet are involved. The onset is sudden, pain is severe, usually confined to the fore foot and more intense during cold weather. The color of the skin, which fails to disappear when the foot is elevated, is dusky red and while the toes are cold, the *dorsalis pedis* artery pulsates. Frequently the fingers and occasionally the tip of the nose present similar vascular phenomena. X-ray is distinctive and diagnostic. It shows atrophy of the terminal phalanges of the toes and in advanced stages—actual disappearance of large portions of these bones.

* From the Department of Surgery, Orthopedic Division, of the Brooklyn Hospital.

Thrombo Angutis Obliterans (Russian Sickness, so-called) is also a blood-vessel disease, characterized by painful, cold, swollen toes, wax-like in appearance. Ninety-nine per cent of the cases occur in Polish, Galician or Russian Hebrews, young males between the ages of 20 and 30, being most frequently affected.

In contrast to Raynaud's disease, as a rule but one foot is involved—and while the parts are red when dependant, they become white when elevated. Pain is often worse at night, walking sometimes relieves it. The most constant symptom is disappearance of pulsation of the dorsalis pedis artery. Of course, when gangrene appears, the condition is too evident to warrant detailed remarks.

show the sclerosed (calcified) vessel. Gangrene is a later or terminal symptom.

Occasionally the initial symptom of diabetes is pain in the forefoot and toes, quickly followed by local death of one or more of the digits, often the fifth. A urine analysis will eliminate the confusion, sugar being found in the specimen.

Only a word about *gout*. The acute type is accompanied by a fever and excruciating pain in the region of the great toe. Other joints are simultaneously involved and the patient of his own volition is bed-ridden. The chronic type is the one with which we are concerned. It is infrequent in this country—common in England—associated with beer-drinking and over-indulgence in food, characterized by recurring dis-

	RAYNAUD'S DISEASE	THROMBO ANGITIS	ERYTHROMELALGIA
1—Sex	Emotional female	Male Hebrew	Male
2—Age	18 to 30	20 to 30	20 to 40
3—Involvement	Bilateral	Unilateral	Bilateral
4—Pain	Intermittent	Worse at night	Constant
5—Redness	Dusky	Bluish	Bright
6—Effect of Elevation	Color unchanged	Becomes white	Color unchanged Pain disappears
7—Effect of cold weather	Worse	Worse	Better
8—Surface Temperature	Decreased (cold)	Decreased (cold)	Increased (hot)
9—Pulsation of Dorsal Artery	Diminished but present	Absent	Full and bounding
10—X-ray	Atrophy of phalanges	Negative	Negative

Erythromelalgia—called oftentimes, "Wier Mitchell's disease" after the man who first described it—is a rare affection of the fore foot, essentially chronic, characterized by pain, redness and swelling. The pain is frequently likened to "Fire in the Skin"—the torture, at times, becoming unbearable. Men between the 20th and 40th years are most frequently affected. It differs from "Russian Sickness" in that exertion such as walking increases, rather than relieves, the pain, the parts are hot, not cold, the swelling is greater and the toes do not "blanch" when elevated. In contrast to Raynaud's disease, heat aggravates the pain. The redness is bright—not dusky and the X-ray shows no bone changes in the phalanges. The essential difference is the presence in erythromelalgia of a full bounding pulse in the dorsal artery.

Arterio Sclerosis—is a distinct and separate disease of the blood-vessels, not infrequently beginning in the arteries of the extremities. Pain in the fore foot is occasionally the initial symptom, usually involving the second toe. It is most common in people over 50 years of age. Coldness and blanching of the affected parts is an early sign. Blueness of the foot and a feebly pulsating dorsal artery in a patient over 50 should put one on their guard. An X-ray will

trengthen pain in the region of the great toe joint. Local heat and tenderness with the palpation of gritty, irregular deposits about the joint, and the finding of tophi (small shot-like nodules on the pinna of the ears) completes the picture.

Perforating ulcer "mal-perforant" is a symptom-complex, described by Nelaton in 1852. It occurs on the sole of the foot at the ball of the great and little toe. A marked callous is noted at the site of predilection, the center of the horny skin layers become softened, peel off, producing a crater, the base of which is covered with sluggish granulation tissue, showing no tendency to heal. It is painless unless secondary infection occurs. An X-ray in the well-developed phase shows osteitis of the shaft of the metatarsal bone nearest the ulcer. This is not a disease entity, but a syndrome, significant of disease of the central nervous system. It may be due to locomotor ataxia, tumors of the spinal cord, etc. Local treatment is futile.

Tuberculosis and *syphilis* do produce lesions in the metatarsal region, tuberculosis causing an osteitis of the tarsal bones—usually in children—while syphilis produces a periostitis usually in adults. Other evidences of these diseases are so marked that the local foot condition is but a part

of the general picture. Mention of them is made merely for the sake of completeness.

Your attention is now invited to a more intensive consideration of the local or focal group. *Hammer toe* may be congenital and even hereditary, but is usually acquired. The characteristic deformity is flexion of the terminal and extension of the proximal phalanx with the formation of a corn on the tip of the toe and a small bursa on the dorsal surface of the projecting knuckle. The condition as a rule is bilateral, the second toe usually being the offender, due to the fact that it is the longest digit and is subjected to constant lateral compression. The earlier the congenital type is treated the better, begin when the child is a few months old if possible—a little metal splint to which the parts are strapped or bandaged should be worn constantly for two to four months, after which the parent should continue stretching the parts three to four times each day. When the child starts to walk—strap the toe by placing a strip of adhesive under the distal phalanx and a second strip over the proximal joint and reapply as often as necessary. Institute rest periods when the skin shows signs of irritation, and during this time resort to a firmly bandaged splint or, if the condition is not too severe, rely on manipulation for a week or 10 days before resorting to re-straping. Of course, a roomy shoe with a soft tip is indicated and such efforts continue so long as a remnant of the deformity persists. If this is not done, recurrence is inevitable.

In the acquired type which occurs in adults—a faulty shoe is always the offender. Proper footwear affords the greatest relief from suffering. Denudation of the callosities is indicated. Moleskin plaster over the painful pressure parts affords relief. In the fixed types of long standing, nothing short of resection of the joint and complete straightening of the toe by the removal of a sufficient bone wedge from both phalanges will affect a cure.

Overlapping fifth toes are congenital defects. They are frequently overlooked in childhood and youth, but the deformity, and consequently the symptom of compression and resultant pain, increasing with age, accounts for the frequency of the assertion by the patient that the condition has been recently acquired. It is not to be denied that a tight shoe may not be the exciting cause, for it often is, but the tendency is undoubtedly congenital. We know of no shoe, nor type of splint which will materially affect correction. If symptoms are present, amputation is the cure.

Morton's toe was first described by Thomas G. Morton in 1876, as a peculiar and painful affection of the fourth metatarsophalangeal joint. It is a clinical entity and certainly a troublesome one to treat.

The affection is of one foot, primarily, but frequently develops into a bilateral complaint. It is characterized by sharp, well-localized pain

which comes on in attacks—at times aggravated by walking, but not necessarily associated with weight-bearing. Not infrequently its occurrence is relevant to the cramped quarters of theatre-seats, but in all events, muscle strain is the basis of an attack. Relief is attained by removal of the shoe and manipulation of the parts. One patient attained relief from no other measure than the immersion of the feet in a cold bath, relief being accounted for in this instance by the muscle relaxation which followed the circulatory shock.

The cause of this characteristic lance-like pain was shown by Sir Robert Jones in 1892 to be caused by the compression of the inter-digital nerve by the subluxed metatarsal head. Relaxation of the plantar fascia is essential to the production of the symptom. The condition is always associated with weakness of the long arch. Any treatment short of definite support to the longitudinal arch, lacks efficiency. Local strapping, such as is afforded by adhesive or the elastic compression of commercial devices, are palliative. Metal supports are poorly tolerated. We prefer a felt pad, supporting both the long and transverse arch, fixed to the foot by adhesive, and changed at weekly intervals, until symptoms have subsided. Relief may not attend one's early efforts, but once attained, a support in the form of a leather covered rubber and metal insole, the exact reduplication of the pad which gives relief, will promote continued improvement. The one important point about this type of disability upon which we insist, is strict co-operation by the patient. If they are not willing to devote a month or six weeks to the experimental phase while arriving at the exact contour for the support which will give the maximum relief, it is best to decline the undertaking. A word about custom-made shoes in this affliction, none have given satisfaction in our hands, and it is an ill-mannered method of side-stepping the issue. The boot-maker will stick to his last if given an opportunity. We should not force such a problem upon him unless we are prepared to supervise his craftsmanship in detail. Occasionally an inner sole with a raise of leather exactly behind the head of the involved metatarsal will suffice, but its effectiveness is fraught with so many difficulties that we always elect the routine above elucidated.

Ring-worm (epidermo-phytosis) occurs about the base of the toes. It is due to a fungus growth, and the source of infection is by direct contact. It can occur through the use of public shower-baths, the promiscuous laundering of socks of an infected individual with the garments of a non-infected person, from the family tub, exchange of foot-wear and the likes. It is most common during the summer months, warmth and moisture encouraging growth.

Breaking of the skin about the basis of the toe, with formation of vesicles (small blisters), itch-

ing of the parts and pain when infection ensues, comprise the clinical picture. Proper treatment consists in breaking the vesicles, the use of salicylic paste as a peeling agent in strengths of 12 to 100 per cent, depending upon the age of the patient, Whitfield's ointment, which consists of 15 grains of salicylic acid and 30 grains of benzoic acid in an ounce of petrolatum anointed on the parts twice daily is a specific. To be sure the patient should be cautioned against bathing in common quarters, and advised to wear white, clean socks until all irritation has disappeared.

Chilblain or pernio is a recurrent affection of one or more toes during cold weather, following an initial, severe exposure of the parts during a previous season. It is infrequent in this locality, due to relatively comfortable living quarters, and the mildness of our winters. Tingling, itching and burning of the toes occur in attacks precipitated by overexercise or sudden exposure of the feet to heat, such as their close approximation to a radiator or open grate. The symptoms are caused by local congestion, frequent attacks of which produce crops of vesicles, these vesicles rupture and expose ulcers which in rare instances slough (Da Costa). Localized, painful swelling of the toes with seasonal periodicity in a young individual should always excite our inquiry into the more intimate history of possible frost-bite. The application of one-half strength iodine ointment is probably the most efficacious measure at our disposal for the relief of pain (Hare). These patients should be instructed to wear comfortable foot-dress and woolen socks throughout the cold season, warm foot-baths at night and the use of a hot-water bag, or better, an electric pad during sleeping hours and cautioned to avoid reexposure to extreme cold.

Hallux rigidus—(stiff great toe joint) is infrequently encountered in civil practice except in the elderly. In military life it is a real factor in foot disabilities—most common in the English army—and provoked, most probably by the wearing of brogans—an inflexible type of shoe—excessive mechanical strain being constantly thrust upon the joint producing fatigue, muscle-spasm and fixation. Manipulation under anesthesia to break up the adhesions with the additional precaution against recurrence by the use of a metatarsal cleat when weight-bearing is resumed, is usually sufficient.

The type with which we, as civilian practitioners, are confronted, is usually in the elderly, the pronated foot is its precursor, excessive strain and its resultant mechanical irritation follows faulty weight-bearing. An underlying tendency to arthritis succeeds in producing rigidity. This type does poorly when operated. Local heat, such as baking or more recently the use of diathermy, is soothing—a soft box shoe with a metatarsal cleat aids in palliation. Persistent, gentle massage and stretching may occasionally accom-

plish restitution of motion sufficient to occasion improved function. It must be discontinued upon the slightest indication of joint reaction (heat, redness or pain about the parts). Forcible manipulation on account of the concomitant arthritis is contra-indicated—for in breaking down the existing barrier to motion, whether they be adhesions or bony outgrowths, new material for the production of greater rigidity is created.

Hallux valgus—is more properly a separate subject. All agree that the deformity follows the persistent use of faulty foot-wear, particularly the pointed toe variety, and yet when we reflect upon the number of people who remain free from this deformity notwithstanding the fact that they subject their feet to an identical type of abuse, there must be some dependent or underlying cause. Painter feels that abnormal proportion of the different segments of the foot, perhaps an abnormally long metatarsal—bringing the metatarsophalangeal joint too far forward in a shoe that might otherwise be of appropriate size for the foot, is the deciding element. Lovett and Jones believe that the constant pull of the flexor hallucis holds the toe, which has previously been deflected outward by the boot, in the erroneous position, and lateral displacement of the tendon results from constant "bow-string" action on the digit. Truslow recently called attention to a few cases in which he feels that the deformity was produced by mal-development of the articular facets of the tarsals, principally the internal cuneiform and scaphoid (navicular) causing the error by virtue of the distorted relation between the proximal head of the first metatarsal and cuneiform.

Be the underlying and exciting causes what they may, the pertinent anatomical irregularities in the fully developed phase are identical. The forefoot is increased in width, there is subluxation of the phalanx on the metatarsal head, rotation of the first metatarsal on its long axis, outward deflection of the four lesser toes, often accompanied by flexion, the appearance of a bony sub-bursal mass on the inner side of the joint, which, by the by, is more often the result of an unduly exposed metatarsal head together with the fact that rotation of the shaft throws into relief the normally less regular inferior surface, than it is an expression of true hypertrophy or bony overgrowth.

Joint changes consist of abnormal relaxation of the internal lateral ligament and inner half of the capsule with a corresponding contraction of the external lateral ligament and external half of the capsule. The articular cartilages in uncomplicated cases are normal. Muscle balance is distorted, the flexor and extensor hallucis tendons are both displaced to the outer side of the joint and through their bow-string action tend to perpetuate the deformity. The adductor hallucis becomes contracted and the abductor its normal antagonist loses its power by virtue of its dis-

of the general picture. Mention of them is made merely for the sake of completeness.

Your attention is now invited to a more intensive consideration of the local or focal group. *Hammer toe* may be congenital and even hereditary, but is usually acquired. The characteristic deformity is flexion of the terminal and extension of the proximal phalanx with the formation of a corn on the tip of the toe and a small bursa on the dorsal surface of the projecting knuckle. The condition as a rule is bilateral, the second toe usually being the offender, due to the fact that it is the longest digit and is subjected to constant lateral compression. The earlier the congenital type is treated the better, begin when the child is a few months old if possible—a little metal splint to which the parts are strapped or bandaged should be worn constantly for two to four months, after which the parent should continue stretching the parts three to four times each day. When the child starts to walk—strap the toe by placing a strip of adhesive under the distal phalanx and a second strip over the proximal joint and reapply as often as necessary. Institute rest periods when the skin shows signs of irritation, and during this time resort to a firmly bandaged splint or, if the condition is not too severe, rely on manipulation for a week or 10 days before resorting to re-straping. Of course, a roomy shoe with a soft tip is indicated and such efforts continue so long as a remnant of the deformity persists. If this is not done, recurrence is inevitable.

In the acquired type which occurs in adults—a faulty shoe is always the offender. Proper footwear affords the greatest relief from suffering. Denudation of the callosities is indicated. Moleskin plaster over the painful pressure parts affords relief. In the fixed types of long standing, nothing short of resection of the joint and complete straightening of the toe by the removal of a sufficient bone wedge from both phalanges will affect a cure.

Overlapping fifth toes are congenital defects. They are frequently overlooked in childhood and youth, but the deformity, and consequently the symptom of compression and resultant pain, increasing with age, accounts for the frequency of the assertion by the patient that the condition has been recently acquired. It is not to be denied that a tight shoe may not be the exciting cause, for it often is, but the tendency is undoubtedly congenital. We know of no shoe, nor type of splint which will materially affect correction. If symptoms are present, amputation is the cure.

Morton's toe was first described by Thomas G. Morton in 1876, as a peculiar and painful affection of the fourth metatarsophalangeal joint. It is a clinical entity and certainly a troublesome one to treat.

The affection is of one foot, primarily, but frequently develops into a bilateral complaint. It is characterized by sharp, well-localized pain

which comes on in attacks—at times aggravated by walking, but not necessarily associated with weight-bearing. Not infrequently its occurrence is relevant to the cramped quarters of theatre-seats, but in all events, muscle strain is the basis of an attack. Relief is attained by removal of the shoe and manipulation of the parts. One patient attained relief from no other measure than the immersion of the feet in a cold bath, relief being accounted for in this instance by the muscle relaxation which followed the circulatory shock.

The cause of this characteristic lance-like pain was shown by Sir Robert Jones in 1892 to be caused by the compression of the inter-digital nerve by the subluxed metatarsal head. Relaxation of the plantar fascia is essential to the production of the symptom. The condition is always associated with weakness of the long arch. Any treatment short of definite support to the longitudinal arch, lacks efficiency. Local strapping, such as is afforded by adhesive or the elastic compression of commercial devices, are palliative. Metal supports are poorly tolerated. We prefer a felt pad, supporting both the long and transverse arch, fixed to the foot by adhesive, and changed at weekly intervals, until symptoms have subsided. Relief may not attend one's early efforts, but once attained, a support in the form of a leather covered rubber and metal insole, the exact reduplication of the pad which gives relief, will promote continued improvement. The one important point about this type of disability upon which we insist, is strict co-operation by the patient. If they are not willing to devote a month or six weeks to the experimental phase while arriving at the exact contour for the support which will give the maximum relief, it is best to decline the undertaking. A word about custom-made shoes in this affliction, none have given satisfaction in our hands, and it is an ill-mannered method of side-stepping the issue. A word about custom-made shoes in this affliction, none have given satisfaction in our hands, and it is an ill-mannered method of side-stepping the issue. The boot-maker will stick to his last if given an opportunity. We should not force such a problem upon him unless we are prepared to supervise his craftsmanship in detail. Occasionally an inner sole with a raise of leather exactly behind the head of the involved metatarsal will suffice, but its effectiveness is fraught with so many difficulties that we always elect the routine above elucidated.

Ring-worm (epidermo-phytosis) occurs about the base of the toes. It is due to a fungus growth, and the source of infection is by direct contact. It can occur through the use of public shower-baths, the promiscuous laundering of socks of an infected individual with the garments of a non-infected person, from the family tub, exchange of foot-wear and the likes. It is most common during the summer months, warmth and moisture encouraging growth.

Breaking of the skin about the basis of the toe, with formation of vesicles (small blisters), itch-

four days as friction tends to break the wire mesh in about this length of time. Recovery may be expected in four weeks. Molded metal supports have been found to be uncomfortable.

Papillomata (often spoken of as a "wart" or "hard corn" by the laity) are true tumor growths of the deep skin layers. Their predilection is for the thickened integument of the ball of the foot. They consist of a mass of compact skin cells with a hard central core, exquisitely tender—and when irritated become cauliflower in character. They are conical in shape, extend through the deep layers of the skin, the base being attached to the plantar fascia. The innocent-looking superficial evidence of their existence is no index of the extent of their deeper distribution.

Removing the upper layers of the excrescence at first gives relief, but the added irritation excites more rapid growth, the pain increases. Similarly unsuccessful has been our attempts to burn them out with such cauterizing agents as silver nitrate. The cure is often worse than the disease.

Believing that they are true tumors which are aggravated by irritation, we prefer the use of a soft rubber and metal insole foot-plate—salicylic acid in a collodian base is employed to remove the superficial layers, and, in 60 per cent of our cases, the growth is under control in three to four weeks and disappears in three to four months. Of the 40 per cent which do not respond to this measure, operation consisting of a wide excision of the entire growth, including its base, and the careful closure of the wound in layers, gives a satisfactory cure in all but a small percentage. Where operation has failed, we have subjected some few to deep X-ray therapy, and a few to radium treatment. We are impressed with the results, and feel that operation in the indolent cases may soon be supplanted by either one of these latter named modalities.

Deutschlander's disease, first described by C. Deutschlander in 1921, is a painful affection of the metatarsal bones, characterized by a sudden onset, persists for a number of months and then subsides. All his cases were in middle-aged women. The sole clinical finding was tenderness over the shaft of the involved metatarsal at the junction of the middle and distal third of the bone—movement of the corresponding toe was painful. X-ray about the ninth week seemingly shows an exostosis. It is a subacute, focal periostitis caused by the plugging of one of the small capillaries by an embolus, or clot in an unusually delicate bone, influenced by prolonged occupational weight-bearing. The treatment is local heat and rest.

Juvenile deforming metatarsophalangeal osteochondritis was first described by Freiberg in 1913 and due to the length of its technical appellation, it would seem excusable to use the less descriptive, but more plastic term "Freiberg's disease."

It occurs, especially during adolescence, frequently in growing girls, pain is referred to the affected metatarsal head, focal tenderness exists, and stiffness of the affected toe, due to muscle-spasm is present. The diagnosis is made by X-ray which shows flattening of the metatarsal head, broadening of the neck and irregularity of the epiphyseal line. The course is short, lasting but a few weeks with an occasional recurrence. Freiberg advises absolute rest by placing the foot in a cast and incorporating a thick pad of felt next to the skin beneath the metatarsal heads. Lateral and upward pressure in this region is applied to the cast while it is setting. When symptom-free, the patient is fitted with a comfortable shoe to which is attached a metatarsal bar, and further support of the arch is afforded by a combination metal foot-plate.

Sir Robert Jones, of Liverpool, is responsible for redirecting our attention to the frequent incident of fracture of the metatarsal bones, often the result of trivial accidents. Tortion motion, such as turning over on one's ankle not infrequently fractures the fifth metatarsal, close to its proximal head. We have seen patients who recall of nothing more violent than stubbing their toe, or hopping on one foot, while executing a dance-step, sustain a fracture of the shaft of the second or third metatarsal. Most of our patients have been over 30 years of age. The pain is focal, more acute on the dorsum of the foot, slight swelling is usual, and by movement of the corresponding toe, crepitus can be felt, X-ray confirms the diagnosis. Sir Robert advises complete rest. We have had no untoward results, while permitting continued weight-bearing, providing that the parts were adequately strapped. Here, again, we use a wire mesh splint upon which is superimposed a felt pad, and the dressing held in firm apposition with the sole of the foot, by taut adhesive bands. Three to four weeks is necessary for a cure.

Just a few words about *claw foot*. I speak of the congenital variety with a high arch, abnormally prominent metatarsal pad and upturned toes. Correction can only be attained by operation. The plantar fascia is separated from the os calcis at one sitting, and the cavus reduced. At the second stage, some three weeks later, the common extensor tendons are exposed through a long curved incision, over the dorsum of the foot tenotomized at the basis of the toes, passed through a tunnel formed by two converging drill-holes in the tarsal bones and transfixed after the method of Stindler. This gives a good foot in a large percentage of cases.

Arthritic metatarsalgia is unlike the static variety in many respects. It is primarily due to the local expression of a general systemic disease affecting the metatarso-phalangeal joints, and producing a chronic inflammation of the parts. The contraction of tendons is not of necessity

placement toward the plantar surface. Weak foot or flat foot invariably accompanies the deformity.

Hallux valgus, therefore, is a complex rather than a simple error, general distortion of the foot supplements the local defect. Disability is not due to the deformity but rather to the pain which is incited by (1) Inflammation of the bursa (bunion), (2) Pressure on the digital nerve by the metatarsal head, similar to the tenderness of a Morton's toe, and (3) Traumatic arthritis, secondary to infection of the bursa, or mechanical irritation an aftermath of faulty joint mechanism.

Treatment of the incipient or moderately advanced stages should consist of a proper shoe, a foot-plate, local splinting or pads, the removal of painful callosities and daily manipulation. The shoe must relieve the joint from undue pressure. A bar or cleat of leather $\frac{1}{4}$ " wide and $\frac{1}{4}$ " thick is nailed to the sole behind the metatarsal head, it may be skived down to paper thickness at its outer border if conspicuousness is objectionable. The inside line of the sole should be straight, the upper leather sufficiently soft and lax to prevent pressure. When the bunion is acutely inflamed, a hole may be cut in the upper, over the swelling and later filled in by a cemented leather patch which is not unsightly. A well-fitting combination metal foot-plate will take the weight off the joint, support the long arch and throw stress to the outer side of the foot. This is preferable to the metatarsal bar especially in women. Men, as a rule, will tolerate both and profit by their united action.

An interdigital splint of moulded rubber, of which there are commercial types, may prevent further local divergence—they are most valuable in the very mild types. If pads are used to protect the bunion they should be circular, their centers punched out and reinforced by lateral adhesive straps so placed as to abduct, or pull the great toe inward. Daily manipulation further aids abduction. It should be forceful, the aim being to stretch the displaced tendons and structures on the outer side of the toe. Acute inflammation of the bursa is best treated by wet dressings and complete rest. For ambulatory dressings we prefer ichthyol to iodine and supplement it with a daily hot foot bath.

Operation fell into disrepute, somewhat, during the world war. It has a place, however, and if undertaken, should have for its purpose the correction of the deformity, the restoration of muscle balance and the re-establishment of normal function. The operation described by David Silver in 1923, most nearly approaches this ideal.

The Mayo operation described in 1908 is a modification of Hueter's and in the hands of the majority of surgeons, is the most efficacious. It more closely meets the needs of the occasional operator and those who are not too familiar with painstaking aftercare.

Various modifications are practiced—the essential feature is the removal of the metatarsal head. The joint is exposed, and with a chisel, the entire head, except for a small portion of its inferior surface, is removed, together with any lateral bony excrescences. The stump is reshaped by filing away all sharp spicules. A flap, either from the bursa or capsule, is turned in over the raw bone surface and sutured in place, the extensor hallucis tendon tenotomized, the capsule closed and overlapped to a degree, sufficient to provide maintenance of abduction.

Any operation is but a step in the cure of hallux valgus. Consistent and persistent aftercare is essential. Early painless motion is advisable. Weight-bearing on the outer border of the foot is begun in from 10 days to two weeks. Splinting in an over-corrected position for three weeks is insisted upon. An old shoe with the inner half of the toe cut out is applied when the splint is discarded, i. e., between the third and fourth week and correction maintained by adhesive strapping. A stocking with a digit for the great toe (made by cutting the ordinary stocking) is worn during this period. After all swelling has disappeared, a new shoe of the inflare type is fitted. Passive abduction should be practiced by the patient daily to prevent recontraction of the external portion of the capsule. When foot form has been restored, our attention should be concentrated on restoring foot function. Plates should be worn and active exercises for adduction and inversion of the forefoot with toe flexion groups insisted upon, over a period of three months, eventually discarding the footplate. The contraindication for operation are:

- 1 Suppurative or ulcerative bursitis
- 2 Osteo-arthritis of the joint
- 3 Persons over 50 who have any evidence of chronic osteoarthritis (rheumatism)
- 4 Women whose sole purpose is the desire to again wear grotesque footwear

Injury to the sesamoid bones under the great toe, deserves detailed comment. They are subject to injury from direct pressure, the sudden descent from a high step or the impact caused by alighting from a moving vehicle, such as a trolley-car, may result in fracture. Pain is focal, confined to the ball of the great toe, unilateral in character, and made worse by dorsiflexion of the digit. X-ray shows the line of fracture. The joint is relieved of direct pressure by a metatarsal cleat. A splint is applied to the toe—we prefer two or three-ply wire mesh, cut in strips, the edges bound with adhesive and the surface covered with felt. This is attached to the sole under the arch, runs forward across the ball of the great toe to its tip, and is firmly fixed in place by adhesive. Its function is to immobilize the parts, rapid union of the fragments being promoted by local rest. The splint should be changed on an average of every

discarded when normal muscle and tendon leverages are restored. Exercises consist of efforts designed to increase toe-flexion, such as attempting to pick up things with the digits, together with adduction and inversion groups aiming to stretch the peronei tendons and heel-cord.

Occasionally all these measures fail to give relief. We are then confronted with the necessity of doing one of two things—either forcibly stretching the parts under anesthesia, and retaining them in a corrected position in a plaster cast for about three weeks, or the forcible manipulation of the forefoot with a lengthening of the heel-cord and immobilization in plaster for from four to five weeks. The lengthening of the heel cord should be a last resort, but no manipulation under anesthesia should be attempted without a distinct understanding with the patient that in the event of failure to properly stretch the structure, the operation is to immediately follow.

the result of faulty footwear, but oft times due to the protective instinct of nature as a means of acquiring rest for the part by limiting function. There are two main types—the infectious and the toxic. The infectious type is usually seen in adults between the ages of 20 and 40. The onset is rather rapid, bony changes have not occurred—and hence X-ray of the joints is negative. Given an overweight woman between the ages of 20 and 40 with a flaccid hind foot, weak ankles and a depressed long arch, add to it the history of long hours of standing on a hard, resilient type of floor, coupled with any one of the following: decayed teeth, infected tonsils, a chronic frontal or maxillary sinusitis, an occasional sore throat (chronic pharyngitis or nasal catarrh), a leucorrheal discharge, the convalescence from a recent attack of typhoid, influenza or pneumonia and the type is visualized.

The immediate indication is the removal of the focus which is causing the trouble. Have those teeth attended to, those tonsils treated or removed as the indication may be, drain that sinus, irrigate that vagina, etc. The point to keep in mind is, that the removal of focal infection must precede local care. When this is done, strap the feet, until all local pain has subsided. Apply a well-fitting insole foot-plate, and advise the use of a heat-lamp 20 to 30 minutes twice a day. Massage and foot exercises are contra-indicated. They will only stir up latent foci and cause a recrudescence of symptoms. You don't have to tell these people to wear comfortable, common-sense shoes—they will.

The *toxic type* is best represented by the elderly, who have so-called rheumatism. Their joints become stiffened, they have cramps in the legs, X-ray shows marked changes in the joints. They have distorted, frowsy feet. Your immediate reaction is a regret that it is not within your power to give them a brand new pair of pedal extremities.

Local measures are palliative—the patient should understand this. Make him a pair of comfortable insolefoot-plates, such as has been previously referred to, advise a light-weight soft leather shoe, and suggest baking for a half-hour twice a day. Diathermy is now being used with more lasting relief than the simple heat therapy, but the condition is in the main intractable. As a routine in our clinic, we give iodides and salicylates in an agreeable menstrum, three to four times a day. Use high colon irrigations once a week when any history of constipation is elicited, and meet other exigencies as they arise. This often means the treatment of a general arthritic condition, which in itself is a big subject.

Static metatarsalgia is rarely an isolated phenomena. Some degree of weak foot invariably accompanies it. The large majority of cases occur in women, and most frequently in those overweight. All admit a passion for high heels,

a low-heeled shoe is unbearable, and as a result the "French-heel pump" appears to them the logical type of foot-gear. The cause is an open secret. I believe we will all agree that grotesque shoes are the basis for this malady. Clinically, the picture is characterized by a tight heel cord, contracted extensor tendons, atrophy of the normal fat pad and its replacement by a painful callous, together with a crop of corns on the dorsal surface of the toes.

Immediate relief is attempted by means of a felt pad and strapping. The pad is so arranged as to afford support for the long as well as the transverse arch, and extends far enough forward to insure protection of the metatarsal heads from further constant pressure. The patient's shoe habit must be changed, a high-heeled shoe ($1\frac{1}{2}$ in to $1\frac{3}{4}$ in) may be worn but a French heel is taboo, a pitch to the shank may be countenanced, but a sheer drop forbidden, the throat must be roomy, regardless of looks and comfortable accommodation afforded the toes. This sounds easy, but I will frankly admit its difficulty of execution. Here is one way out of it—tell them that you know the shoe looks atrocious, but that if they will wear it for three months they may wear any shoe they wish. This assertion may leave one open to criticism, but on reflection this is not so. At the end of three months their feet have so regained their contour that the freakish shoe is an impossibility.

It is in this type that baking and massage are invaluable aids in treatment. These modalities should be commenced as soon as the acute pain has subsided and the pad and straps dispensed with (3 to 4 weeks). The foot and leg should be baked for 15 to 20 minutes daily, massage follows for a period of 10 to 15 minutes, preferably by a masseuse, and the conclusion of the seance from 10 to 15 minutes is taken up with forcible stretching of heel cords and common extensors, their relaxation being the essential feature upon which permanent relief is based.

Promising the gradual relief by frequent strapping, the adoption of a proper shoe and the acquiescence to a regime of massage and stretching, one is prepared to apply a foot-plate. I know of no more distressing thing than to attempt the application of a foot-plate to a person with a moderately severe static metatarsalgia, without previously preparing the way. It is fatal, because the fundamental basis of tight heel-cord and extensor tendons has been overlooked. We do not hold to the wisdom of all-metal foot-plates in this affection, the combination leather and metal insole, with a sponge rubber insert, is infinitely more satisfactory. By preference they are made for the individual by our brace-man from a sketch. Commercial arches, even of this general design, are, in our experience, a failure.

Exercise supplements the fitting of plates, which we look upon as a palliative measure to be

After the blood disintegrates, it becomes loaded with a waste and useless material which must be dumped and will be dumped along the line of least resistance, which in the asthmatic is the mucous membranes of the head and air tubes.

Now, if at this prodromal stage the drinking water be uncontaminated and the diet scientifically manipulated so as to render it compatible with the asthmatic's disturbed nutrition, and if the weather conditions be favorable, this oncoming attack may be successfully averted without the aid of systemic chemicals or medicines.

But if the weather conditions are unfavorable, such as a coryza (hay-fever) or influenza weather, in order to prevent the oncoming attack, systemic chemicals or chemicals that are normally found in the body must be administered in the form of medicines as indicated to correct the body chemistry.

When the deficient normal body chemicals are determined and administered in accord with a proper diet, the oncoming attack will generally be prevented or rendered non-incapacitating, no matter what the weather conditions may be.

After the disturbed nutrition and perverted metabolism have altered the chemistry of the lymph and caused the unstable blood of the asthmatic to disintegrate, if the process is not averted, the circulation of the blood and the propulsion of the lymph carry the same to the lungs, where the lungs in the performance of their glandular function, mix and filter the lymph and blood, depositing the inferior, or waste products in the mediastinal, bronchial and tracheo-bronchial glands.

The blood begins first in the asthmatic to dump its waste products through the mucous membranes of the head and larynx, producing first a coryza (hay-fever) and laryngitis.

After the coryza stage, the laryngeal pouches are filled with thick, tenaceous mucus, which shoves the ventricular bands or false vocal cords into the lumen of the larynx sufficiently to produce a valvular action which shuts off the air and produces an attack.

The agony of the patient at this period surpasses description and one can read the pathology in his very attitude.

This laryngeal dyspnoea loads the bloods with carbon dioxide, interferes with the circulation, dilates and congests the capillaries of the bronchi, bronchioles and air cell walls, rendering them erotic and non-collapsible. These processes rapidly combine to result in the asthmatic respiratory block.

After about twenty-four hours of this laryngeal dyspnoea the glands undergo a resolution and degeneration with the expulsion of thick mucus, which is in thick lumps the size of a pigeon's egg, and is of a tough, tenacious, viscid consistency which gives it an appearance of fat

tissue and enables one to pick it up and handle it about.

On inspection this mucus is found to contain several little grayish pearly balls which on being unraveled and viewed under the microscope are found to be composed of delicate convoluted spirals (Curschmann's) made up of numerous individual filaments. Other portions of the sputum under the microscope without staining, are found to contain numerous leucocytes, exhibiting bright yellowish, coarse granulations, among which are numerous colorless, pointed octohedral crystals (Charcot Leyden's). Numerous eosinophile granules, which are derived from ruptured eosinophile cells, are also found scattered throughout the field.

The composition of this mucus shows that it has been dumped by the disintegrated unstable blood of the asthmatic. The sputum of the asthmatic is frequently tinged with blood and the asthmatic usually has a bloody taste in his mouth.

The process of engorgement of the mucous membrane and glands and pressure from the enlarged glands rapidly extend downward, involving the trachea and bronchi, producing attack after attack, until the blood changes or drifts over to the anemic variety. A new vicious circle is now established, the anemo-vascular.

In this anemo-vascular variety of asthma with the dilated blood vessels and capillary congestion which result from the asphyxia of the preceding attacks, also generally with an hypertrophied right heart and emphysema, the asthmatic is in a wretched condition from which his deliverance becomes a difficult problem.

The blood now at an interval between attacks has a low hemaglobin scale, flows in rapid-forming, large, thin, watery drops with a low viscosity, slow coagulation, marked but scant rouleau formation with island-like groups and a low red cell count. Such an asthmatic has attacks night after night, often never attempting to rest in bed for years at a time.

This interval of freedom is seldom attained, as the attack is more or less constant, abating enough day times to allow the patients to be up and about, while some follow their usual occupations.

During attacks the blood resembles that of the toxic leucocytic type of asthma.

The capillaries of the alveoli and bronchioles in this type of asthma are so congested that the percussion note is solid and there is not enough air entering the alveoli to produce a wheeze in the lower lobes of the lungs. These lungs resemble a water-soaked sponge. The dyspnoea of this type resembles that often found in chronic non-febrile tuberculosis.

When the asthmatic is on the delicately balanced respiratory margin characteristic of this variety of asthma, the least deleterious change in the chemical or dust composition of the in-

THE BIOCHEMICAL METABOLIC BLOOD ORIGIN OF ASTHMA AND ITS SCIENTIFIC PREVENTION *

By GEORGE N JACK, M D

BUFFALO, N Y

TWENTY-SIX years ago, I first maintained that asthma was of blood origin and not nerve reflex or spasm. Today, after a study of 1,431 cases, I maintain that I have collected enough clinical and scientific material to positively demonstrate that fact.

The field is large, embracing all the physical laws pertaining to life, also acquired and inherited peculiarities, as shown by a brief synopsis of the work.

The clinical notes and records of cases treated as chemically and clinically indicated according to recent discoveries, most convincingly demonstrate that the reason that asthma has always been such a dreaded disease to have and such an intractable and discouraging one to treat, was due to the fact that its etiology and pathology were not known.

There is no specific cause nor treatment for asthma.

In primitive medicine all dyspnoea or shortness of breath was classed as asthma.

With the discovery of urinalysis and a knowledge of the functions of the kidney, it was discovered that a diseased kidney would produce dyspnoea, which gave a renal asthma, and asthma proper.

With the discovery of the stethoscope, it was found that a diseased heart would produce a dyspnoea, which gave a renal asthma, a cardiac asthma and asthma proper.

With the discovery of the microscope and a knowledge of the morphology of the blood, it was discovered that certain blood diseases as pernicious anaemia and leukaemia were accompanied with dyspnoea, which gave a renal asthma, a cardiac asthma, a pernicious anaemic or leukaemic asthma and asthma proper.

There remained to be demonstrated the lymph propulsion and exchange, the glandular action of lung tissue, the pathology of asthma and the biochemical metabolic blood changes that produce asthma. With the demonstration of these facts, it follows that asthma is a biochemical metabolic blood disease with dyspnoea as its late symptom and is not a disease due to a spasmodic contraction of the air tubes, as heretofore supposed. Dyspnoea and asthma, therefore, can no longer be used as synonymous terms.

That the lymph circulated has long been an acknowledged fact, but how it circulated, where it went and whence it came, no one has determined before, or even offered a good guess.

The solution of the lymph propulsion and ex-

change problem² not only enables us to scientifically treat asthma, but, it, together with the discovery of the fact lung tissue performs a glandular function³, has a great and important bearing on all respiratory diseases from pleurisy to tuberculosis.

Asthma cannot be scientifically treated without a knowledge of the biochemical metabolic blood origin of the disease, the lymph propulsion and exchange and the glandular action of lung tissue.

My study of asthma has convinced me that, while the unstable blood of many asthmatics is sensitized for life to certain hemolytic phenomena or gases, the physician who is familiar with the etiology and pathology of asthma can educate eighty per cent of his patients how to successfully cope with their problem.

The old axiom, "Know thyself," is of vital importance to the asthmatic. The education of the asthmatic is an essential factor in the scientific prevention of asthma. The asthmatic must be educated as to what the different blood disintegrating agents are and then taught how to avoid them.

I maintain that there are three well-defined vicious circles of asthma, namely, the lymphocytic, the toxic-leucocytic and the anemo-vascular.

A brief synopsis of one of these vicious circles, the toxic-leucocytic, is as follows. The asthmatic has an unstable blood. This unstable blood has been either inherited or acquired through generally a long period, perhaps years, of dietetic errors or unfavorable environments.

The asthmatic's unstable blood is always playing close to the wheeze or dyspnoeic margin.

From thirty minutes to two or more weeks before an attack of dyspnoea, the nutrition, metabolism, blood and lymph, or the body physico-chemicals of the asthmatic are unusually disturbed or perverted, as manifested by polyuria, a coated tongue, flatulency, indicanuria, chyluria, acidosis or occasionally glycosuria.

The stools are generally toxic, putrid and alkaline with a rotten egg or meat odor, or they are acid, gaseous, fermenting with a disgusting, irritating, penetrating odor, often showing mucus and particles of undigested food.

This disturbed nutrition produces toxic substances or deleterious chemical re-agents that, when absorbed from the intestine by the lymph and blood, either in the form of gases, liquids or putrefactive alkaloids, so interfere with the chemistry of the asthmatic's unstable blood that it disintegrates. This blood disintegration is generally ushered in with a chill, a feeling of depression or mental anxiety.

* Read by invitation, October 13, 1925, before The Medical Society of Bay Ridge, Brooklyn, N Y

action This must be accomplished by manipulating the diet and occasionally administering alkalies as sodium bicarbonate Some of the foods that tend to increase the alkalinity of the blood are oranges, lemons, peaches, cantaloupes, beans, potatoes and fresh vegetables Some of the foods that tend to diminish the alkalinity of the blood are prunes, cranberries, meats and cereals Where there is any tendency to edema salt should be restricted

The rechemistration of the asthmatic's unstable blood must be assisted by prescribing foods that contain the deficient blood chemicals and that are rich in vitamins or chlorophyl and protoplasm, as found in green vegetables, eggs, rare beef, milk, cod liver oil, etc., and by prescribing sunshine, outdoor atmospheric electro-magnetism, occupation, recreation, change of environment, etc

As soon as the blood draws its deficient chemicals from the prescribed hygiene and dietetic treatment, their administration in the form of medicine should be stopped, for if they are not stopped, it will prevent the blood from drawing them from the food, sunshine and environment

When the blood is deficient in two or more blood elements, they should be administered in preparations containing but one of the indicated chemicals, so that they can be stopped, or diminished at the first sign of an untoward result. The successful management of a case depends largely upon the observation of this principle

If a chemical analysis of the normal living person's body were to be made it would be found to be composed of a certain percentage of the following elements, namely hydrogen, oxygen, sulphur, chlorine, iodine, fluorine, nitrogen, phosphorus, carbon, silicon, potassium, sodium, calcium, magnesium, arsenic and iron. If the same chemical analysis were to be made of the asthmatic's body his system would be found to be deficient in many of these elements

It is my custom in the rechemistration of the asthmatic's unstable blood to administer the deficient blood chemicals when indicated, one chemical only in each preparation, so that it can be stopped or diminished with any untoward result, or as the blood draws the deficient chemical from the prescribed diet and sunshine. For this reason, I administer when indicated the following chemicals in the form of soluble tablets to be taken in hot water, in aqueous solutions, oil preparations, or soft mass pills to be crushed before taking, ammonium acetate, ammonium chloride, arsenic, calcium sulphide, calcium chloride, iron from bran, phosphorized cod liver oil, potassium nitrate, sodium nitrate, potassium citrate, sodium phosphate, sodium silicate, sulphur, sodium iodide, manganese binoxide or magnesium oxide

During blood stabilizing meteoric telluric phenomena such as generally prevail at the summer

and winter solstice, the asthmatic should when possible discontinue or diminish his medicinal blood rechemistration, to be resumed again if indicated during the blood disintegrating fall and spring equinoxes

The prevention of asthma is not a day's work but a life's work, hence the asthmatic should be treated at home and by his family physician

The unstable blood of the asthmatic has no single pathognomonic feature, but its collective manifestations positively demonstrate its instability

There is no special toxin that disintegrates the unstable blood of the asthmatic, but after it disintegrates from any cause, as a capillary congestion of the air tubes with its resulting dyspnea, caused by dry frosty air, or a high viscosity of the blood with its resulting dyspnea, caused by overeating, it rapidly generates toxins

Some of the toxins that disintegrate the asthmatic's unstable blood are toxic gases, putrefaction, heat humidity retention toxin, cloudy, chilly, humidity toxic gas combinations, fatigue intoxication and the hypodermic injection of a raw proteid

Inhaled non-toxic agents that congest the respiratory capillaries as dry, frosty air and certain dusts as lime dust, will produce dyspnea, which if long continued will through sub-oxygenation, disintegrate the blood so that an attack of asthma will result.

Lime is a caustic that must be kept out of children's reach and kept out of the eyes

Asthmatics that keep pans of unslaked lime on their bedroom floors to absorb blood-disintegrating gases and give off blood-stabilizing gas as chlorine, should have the lime sifted out of doors, after it partly slakes, to avoid inhaling the lime dust

The relation between summer autumnal coryza or asthma and humidity, temperature, gas or dusts could be demonstrated in the oxygen chamber of the Rockefeller Institute for Medical Research. The effect of any gas or dust could be determined by adding it to the room

The application of these simple principles means much to the asthmatic who has suffered the horrors of asthma for years, as shown by the following case

Case No 1100, July 6, 1920, Mrs G A K, Buffalo, N Y, age, 55, weight, 100 lbs, married 38 years, 11 children, 6 living, influenza, 1918, in bed four weeks, fever and some asthma Asthma all her life. Did not have much asthma in warm or real cold weather, was worse in the fall and spring or any time during chilly, cloudy weather During attacks would always sit up nights For the last two years, asthma has been very severe, causing her to sit up all night a great many nights and from 2 A M every night The last four nights before consulting me, sat up all night and was also very bad during the days

haled air, as a lucifer match, hydrochloric or muriatic acid fumes, animal odors, an ill-smelling kerosene lamp, night gases, cold dry air, animal excreta, gases and dusts of all and every kind will suffice to precipitate an attack, either by irritating the already congested mucous membrane of the air tubes, adding more poison to the asthmatic's already toxic system, or by taking up the room needed for oxygen, of which, in the asthmatic when he is loaded for an attack, there is none to spare

Then again on the circulatory side of this delicately balanced respiratory process of this variety of asthma, any agent or act which congests the capillaries, as a cough, laugh, exertion or emotion will often suffice to precipitate an attack

The prognosis of asthma in children before puberty is more discouraging than in adults, owing to their richness in lymphatic tissue and their inability to cooperate intelligently

In the scientific prevention of asthma, its treatment both dietetic and medicinal must be varied according to the vicious circle and the different stages of a given vicious circle. Or, in other words, nothing is prescribed unless it is first indicated by some simple office laboratory or clinical investigation, and the untoward results of the prescribed agent must always be kept in mind, no matter whether it be sunshine or sodium bicarbonate

The brownish coloration of the polynuclear leucocyte with the iodine stain as emphasized by Cabot in general toxemia, abscess, well marked anaemia, pneumonia and asthma, I have interpreted in asthma as an amyloid degeneration indicative of impaired nutritive function and the administration of my loppered milk diet

Indicanuria indicates a toxic blood and no matter whether due to a heat humidity or arising from or aggravated by an intestinal toxemia, it indicates the withholding of meat

A blood slow to coagulate indicates the administration of gelatine

An acid-fermenting, gaseous stool indicates intestinal fermentation and the withholding of sweet milk and certain vegetable foods, as potato and cabbage

A blood showing a poor red cell count indicates anaemia and the feeding up on beefsteak, spinach, raw eggs and other blood-making foods

A high blood pressure, a thick sputum or a rapid blood coagulation indicates potassium nitrate (saltpetre)

A blood loaded with lymphocytes, showing a return to the infantile type, denotes the withholding of milk, raw oysters and other lymphogenous foods

If there is much flatulency the dietetic or functional cause must be sought and corrected

From the character of the sputum it is to be determined whether an expectorant, as ammonia

chloride or an agent that contracts the relaxed mucous membrane capillaries as adrenalin chloride, is to be administered

An acidosis indicates the administration of alkalis and a change in diet

Hepatic torpor or oxaluria indicates the administration of acids

When the capillaries are congested and relaxed they are tightened up as indicated by adrenalin, pituitrin, strychnine, atropine, quinine, capsicum, cinnamon, ginger, alcohol digitalis, ergot, arsenic, boneset, wintergreen, oxygen, spinal cupping, hot water drinks, massage, etc

When the metabolism is below par as indicated by much flatulency it is stimulated by nitro-muriatic acid, dilute.

A dilated right heart may indicate digitalis, strophanthus or stramonium

A low blood pressure indicates strychnine.

A hemorrhagic tendency indicates cinnamon and calcium chloride

A purulent sputum indicates turpentine or oil of eucalyptus administered either orally by sprays or steam inhalations or absorbed from the skin by rubs or as turpentine stupes

The absorption of poison gas from the gastrointestinal tract when there is flatulency should be prevented by administering charcoal to absorb it, or compound spirit of ether (Hoffman's Anodyne) to eliminate it.

A subnormal temperature indicates alcohol, which is best given in the form of gin

Excessive bronchial secretion indicates a blood low in sulphur

A rapid blood coagulation indicates potassium citrate

When the blood shows a high viscosity and rapid coagulation with a slow, dirty, grayish-brown hydrogen peroxide reaction, iodine is indicated

A drop of blood showing a slow, brownish-white hydrogen peroxide reaction indicates the administration of iron

After the blood disintegrates, the disintegrated material must be eliminated from the blood by starvation, the drinking of hot water, cathartics, such as castor oil and mineral oil, equal parts, or cascara and by diuretics as potassium sodium or ammonium acetate or sweet spirit of nitre, diuretin or some other preparation of caffeine and expectorants as saltpetre smoke, ipecac or ammonium chloride. Cathartics that increase the viscosity of the blood as epsom salts should not be used

Iodine, when indicated in asthmatics with a goiter should be administered tentatively, although asthmatics seldom have the hyperthyroid type

The asthmatic's blood should be kept slightly plus in alkalinity as indicated by the reaction of the urine, keeping the urine slightly acid in re-

action This must be accomplished by manipulating the diet and occasionally administering alkalies as sodium bicarbonate Some of the foods that tend to increase the alkalinity of the blood are oranges, lemons, peaches, cantaloupes, beans, potatoes and fresh vegetables Some of the foods that tend to diminish the alkalinity of the blood are prunes, cranberries, meats and cereals Where there is any tendency to edema salt should be restricted

The rechemistration of the asthmatic's unstable blood must be assisted by prescribing foods that contain the deficient blood chemicals and that are rich in vitamins or chlorophyl and protoplasm, as found in green vegetables, eggs, rare beef, milk, cod liver oil, etc., and by prescribing sunshine, outdoor atmospheric electro-magnetism, occupation, recreation, change of environment, etc

As soon as the blood draws its deficient chemicals from the prescribed hygiene and dietetic treatment, their administration in the form of medicine should be stopped, for if they are not stopped, it will prevent the blood from drawing them from the food, sunshine and environment

When the blood is deficient in two or more blood elements, they should be administered in preparations containing but one of the indicated chemicals, so that they can be stopped, or diminished at the first sign of an untoward result. The successful management of a case depends largely upon the observation of this principle

If a chemical analysis of the normal living person's body were to be made it would be found to be composed of a certain percentage of the following elements, namely hydrogen, oxygen, sulphur, chlorine, iodine, fluorine, nitrogen, phosphorus, carbon, silicon, potassium, sodium, calcium, magnesium, arsenic and iron If the same chemical analysis were to be made of the asthmatic's body his system would be found to be deficient in many of these elements

It is my custom in the rechemistration of the asthmatic's unstable blood to administer the deficient blood chemicals when indicated, one chemical only in each preparation, so that it can be stopped or diminished with any untoward result, or as the blood draws the deficient chemical from the prescribed diet and sunshine For this reason, I administer when indicated the following chemicals in the form of soluble tablets to be taken in hot water, in aqueous solutions, oil preparations, or soft mass pills to be crushed before taking, ammonium acetate, ammonium chloride, arsenic, calcium sulphide, calcium chloride, iron from bran, phosphorized cod liver oil, potassium nitrate, sodium nitrate, potassium citrate, sodium phosphate, sodium silicate, sulphur, sodium iodide, manganese binoxide or magnesium oxide

During blood stabilizing meteorologic phenomena such as generally prevail at the summer

and winter solstice, the asthmatic should when possible discontinue or diminish his medicinal blood rechemistration, to be resumed again if indicated during the blood disintegrating fall and spring equinoxes

The prevention of asthma is not a day's work but a life's work, hence the asthmatic should be treated at home and by his family physician

A blood slow to coagulate indicates the administration of gelatine.

An acid-fermenting, gaseous stool indicates intestinal fermentation and the withholding of sweet milk and certain vegetable foods, as potato and cabbage.

A blood showing a poor red cell count indicates anaemia and the feeding up on beefsteak, spinach, raw eggs and other blood-making foods.

A high blood pressure, a thick sputum or a rapid blood coagulation indicates potassium nitrate (saltpetre).

A blood loaded with lymphocytes, showing a return to the infantile type, denotes the withholding of milk, raw oysters and other lymphogenous foods.

If there is much flatulency the dietetic or functional cause must be sought and corrected.

From the character of the sputum it is to be determined whether an expectorant, as ammoma

chloride or an agent that contracts the relaxed mucous membrane capillaries as adrenalin chloride, is to be administered.

An acidosis indicates the administration of alkalis and a change in diet.

Hepatic torpor or oxaluria indicates the administration of acids.

When the capillaries are congested and relaxed they are tightened up as indicated by adrenalin, pituitrin, strychnine, atropine, quinine, capsicum, cinnamon, ginger, alcohol, digitalis, ergot, arsenic, boneset, wintergreen, oxygen, spinal cupping, hot water drinks, massage, etc.

When the metabolism is below par as indicated by much flatulency it is stimulated by nitro-muriatic acid, dilute.

A dilated right heart may indicate digitalis, strophanthus or stramonium.

A low blood pressure indicates strychnine.

A hemorrhagic tendency indicates cinnamon and calcium chloride.

A purulent sputum indicates turpentine or oil of eucalyptus administered either orally by sprays or steam inhalations or absorbed from the skin by rubs or as turpentine stupes.

The absorption of poison gas from the gastrointestinal tract when there is flatulency should be prevented by administering charcoal to absorb it, or compound spirit of ether (Hoffman's Anodyne) to eliminate it.

A subnormal temperature indicates alcohol, which is best given in the form of gin.

Excessive bronchial secretion indicates a blood low in sulphur.

A rapid blood coagulation indicates potassium citrate.

When the blood shows a high viscosity and rapid coagulation with a slow, dirty, grayish-brown hydrogen peroxide reaction, iodine is indicated.

A drop of blood showing a slow, brownish-white hydrogen peroxide reaction indicates the administration of iron.

After the blood disintegrates, the disintegrated material must be eliminated from the blood by starvation, the drinking of hot water, cathartics, such as castor oil and mineral oil, equal parts, or cascara and by diuretics as potassium sodium or ammonium acetate or sweet spirit of nitre, diuretic or some other preparation of caffeine and expectorants as saltpetre smoke, ipecac or ammonium chloride. Cathartics that increase the viscosity of the blood as epsom salts should not be used.

Iodine, when indicated in asthmatics with a goiter should be administered tentatively, although asthmatics seldom have the hyperthyroid type.

The asthmatic's blood should be kept slightly plus in alkalinity as indicated by the reaction of the urine, keeping the urine slightly acid in re-

son may drink ten quarts of water in ten hours and not eliminate over a pint by the kidney

In Buffalo, July 6, 1925 when three deaths were reported from the heat wave, the noon temperature was only 78 degrees, but the humidity was high or 81

Heat humidity hemolytic crises as congested capillaries, swollen extremities, edema, summer autumnal coryza, asthma, heat exhaustion or sunstroke, eczema, cholera infantum, cholera morbus, etc., should be guarded against by the measures already outlined and also by the restriction of cereals and meats

A heat humidity hemolytic crisis is also manifested by a small, dark drop of blood with a high viscosity and rapid coagulation, with a rapid, dirty grayish-brown hydrogen peroxide reaction, and scant, brown, highly acid urine with a high specific gravity and indicanuria

Although many of my patients have gone from fifteen to twenty years without an attack and consider themselves permanently cured as shown by the following case, yet I consider the unstable blood of the asthmatic to be sensitized for life to certain blood disintegrating agents which should always be guarded against

Case No 365—Referred to me by the late Dr H P Jack, Sept. 2, 1911, Master F A., Almond, N Y, age 13, weight, 81 lbs Had asthma for 3½ years, attacks coming on about every three weeks and lasting for two weeks During attacks would have to sit up in a chair from 1 to 3 A. M Had diarrhoea and frequent urination before attacks

F H Aunt, asthma and rheumatism, mother, migraine, father, salt rheum or eczema.

This patient has practically had no asthma since he began treatment, or for thirteen years to date of last report, Aug 4, 1924

If the asthmatic, thinking himself cured, neglects to return for the required examinations and analyses and stops the treatment before his blood, urine, stool and sputum show that he should and begins to wheeze, he has no one to blame but himself

Asthmatics have been lied to and defrauded so much by advertised nostrums, some of which are dangerous protoplasmic poisons or habit-forming drugs, that it is extremely difficult to convince them that asthmatic seizures or what to them constitutes asthma, can be scientifically and satisfactorily treated But when the asthmatic is once convinced that some one is telling the truth about asthma and is able to rob the disease of its indescribable horrors, he will travel many miles and undergo great hardships to consult such a physician

After a physician sees numerous cases like the following, he is convinced that the prevention of uncomplicated asthma can be accomplished.

Case No 253, June 10, 1910, Mrs H, Snyder, Canada age 38, farmer's wife, five children At

seventeen had inflammation of the bowels, later congestion of the lungs, asthma when an infant, free from asthma from infancy to age eighteen, from eighteen until date of consultation had asthma in a very distressing form, never knowing when attacks would come or go, almost every day or night and not influenced much by seasons; warm, muggy weather bad for her asthma, had to sit up all night while having an attack, took morphine nearly every night and did not receive much relief Mother had sent her to Denver and Muskoka with no benefit

One week after beginning treatment, reported no asthma after the first twenty-four hours' treatment Slept soundly every night Still coughed considerably and felt a little weak, but began to do light work One night she was afraid she would have an attack and sent fourteen miles for morphine, but did not need it

No asthma one week later, stronger and did more work than she had been able to do for years

A week later reported no asthma, stronger, doing her own housework, taking care of dairy, hoeing in the field, raking and loading hay

This patient took two quarts of buttermilk a day with her prescribed diet and she gained in weight, her weight when she began treatment was 134 lbs and on Sept 26, 1911, it was 148 lbs She had a few reminders of asthma when she neglected to follow out her prescribed treatment on April 10, June 30, August 22, Sept 6, 1911, and Jan 22, 1912

On March 14, 1913, a reminder of asthma, followed by tonsillitis which was followed by inflammatory rheumatism

July 23, 1914, reported only two mild attacks during the last year, but considerable rheumatism

October 8th, reported no asthma and claimed that she was cured of the morphine habit.

February 8, 1916, reported no asthma but still considerable rheumatism

July 30, 1916, reported no asthma but rheumatism

Asthma often abates at puberty In women, attacks of asthma often accompany menstruation Many women develop asthma at the menopause Asthma often leaves in old age with the development of senile anaemia and atrophy of lymphatic tissues Asthma is frequently accompanied by or alternates with eczema, rheumatism or migraine and in heredity, they frequently follow Mendel's Law, parent asthma, child migraine, eczema or rheumatism, grandchild asthma The unstable blood of the asthmatic thus constitutes a more or less permanent defect

After the asthmatic's unstable blood disintegrates it flows in dark, slowly formed drops with a high hemoglobin scale, a high viscosity, a rapid coagulation and a thick consistency, showing a slow, dirty, grayish-brown hydrogen peroxide

July 13th—No asthma, sleeping the best she has ever done. Taking two quarts of thick milk a day. Vegetables added to diet.

May 31, 1921—Gained 17 lbs in weight. No asthma.

May 5, 1922—Last report, has had practically no asthma since beginning treatment. While under observation she was in excellent health and did her own housework.

Climatic, telluric, meteorologic, atmospheric or weather conditions favorably or unfavorably affect the unstable blood of the asthmatic or coryza (hay-fever) subjects.

A meteorologic condition that will affect one subject favorably may affect another unfavorably. A climatic condition that will affect an asthmatic favorably at one stage of his asthma may affect him unfavorably at another stage of the disease.

For the asthmatic or coryza subject to undertake to find a climate compatible with his make-up is a discouraging task and generally ends in disappointment.

The effect of weather conditions upon the unstable blood of the asthmatic and coryza subjects has resulted in a thousand superstitions.

Asthma and metabolic or climatic coryza or the so-called June colds, hay-fever, la grippe and influenza are amendable conditions when scientifically treated from a nutritional, metabolic, blood, etiologic standpoint.

While we cannot change the weather factors, we can so fortify the system that it will stand unfavorable weather without an attack.

All unstable bloods do not originate from the nutrition or alimentary tract, and in such cases an interference with a self-selected diet only as indicated by a test diet will often do irreparable harm, if not result in a new vicious circle that is very difficult to correct. Thus indican and other deleterious substances in the urine come from a toxic blood which may or may not have originated from an intestinal disturbance. The origin of a toxic blood then must be determined by a study of the blood, urine and stool.

No treatment for asthma will be satisfactory unless the asthmatic's unstable blood is protected from hemolytic agents that it may be extremely sensitized to as a chilly or heat humidity and musty, mouldy, decomposing sewer, swamp or animal gases. The protection in some cases can be obtained only by a change in residence, climate or occupation.

The asthmatic should be treated at home so that his treatment can be adjusted to his home environment.

The following case shows how the asthmatic depends upon the medical profession.

Case No 250, Dec 6, 1909, Mr W P, age 56, occupation, traveling pharmacist, syphilis 30 years ago, paralysis vocal cords 18 years ago

from which he never completely recovered, spotted fever 18 years ago, asthma began twenty-two years ago while in Denver, Colorado, altitude, climate or seasons of no benefit, asthma all the time, sits up every night and labors for breath, has tried everything, father was a prominent physician, at one time U S Surgeon-General.

After the first three days he reported that he was feeling and breathing better and had sat up only one hour the night before.

The following week he reported that he slept all night, attended to his furnace and ran upstairs, things he had not been able to do for the last twenty-two years.

This patient had practically no more asthma except a reminder, December 28, 1916, which lasted for two weeks when he neglected to follow out instructions. Patient died January 23, 1919, of dilated, intermittent heart.

There is no disease that more positively shows the relation between the body chemistry, food, water, air and sickness than asthma.

During hot, windless, cloudy or partly cloudy, humid periods of weather, when the temperature is above 86 degrees and the humidity above 70, heat humidity retention hemolytic crises should be guarded against by administering cathartic doses of castor oil and mineral oil every morning and taking nothing but orange juice and hot water for breakfast.

They should also be guarded against by the drinking of plenty of water and by keeping as cool as possible by protection from the sun, by running water fountains, electric fans or riding in a covered, open vehicle or exercising vigorously enough while drinking lots of water to produce a free perspiration.

A hemolytic crisis caused by chilly, humid, windless nights with a heavy dew, or nights when the temperature falls below 62 degrees, should be guarded against by heat and light, the best light being an electric light.

The asthmatic should also be protected from hemolytic, night atmospheric gases upon these nights, by a gas filtering ventilator, unslaked lime on the floor, camphor gas, naphtha balls and pine needles, also by burning saltpetre if distressed by asthmatic dyspnoea. If out of doors on these nights after dew falls, he should protect himself by the U S army gas mask.

Heat, humidity, hemolytic crises are due more to a retention of end metabolic products partly through a dilatation of the capillaries than to a loss of blood fluid by perspiration.

In hot, dry or arid locations as deserts where perspiration is increased by its rapid absorption, there is less disturbance from heat than in windless, humid locations where perspiration is retarded by its accumulations upon the skin.

In extremely hot, arid, desert locations a per-

ADMINISTRATIVE IDEALS

When the President of the Medical Society of the State of New York assumes office, he finds a rich heritage of precedent on which to base his administrative policies and activities. The outstanding accomplishments of the last administration have been the passage of a Practice of Medicine Act, the establishment of an extensive system of graduate medical education, and the formation of a harmonious co-operation of the medical profession with the official departments of health and the great lay public health organizations. But each of these lines of work is only begun. Now that

the Practice of Medicine Act has been passed and signed, it must be put into operation, graduate education must be extended, new courses prepared, new teachers secured, and physicians must bestir themselves in popular medical education and disease prevention in order to do their proper share of the work in which lay organizations find their peculiar field. Carrying out these policies will afford the officers of the State Society abundant opportunity for the exercise of original thought and constructive building.

GEORGE M. FISHER,

reaction. The cells are glued together forming an opaque, shapeless, adherent mass and when differentiated by extra pressure on the cover glass, many of the erythrocytes are disintegrated, the leucocytes increased, with many eosinophiles.

The urine is scant, dark brown or bloody brown with a high specific gravity and often showing indican.

At this stage, the blood's equilibrium is reversed and its existence depends upon the immediate dumping of its disintegrated material. This is dumped along the line of least resistance or the air tubes.

At this stage the blood-dumping process should be aided by the administration of castor oil and mineral oil, the inhalation of potassium nitrate smoke (saltpetre) and the withholding of all foods, except hot water and orange and lemon juice.

As soon as the blood has dumped its disintegrated material and reached its nourishment-absorbing equilibrium, it is shown by the blood flowing in large, rapid-forming drops with a low hemoglobin scale, a low viscosity, a slow coagulation, a thin consistency and a rapid, pinkish-white hydrogen peroxide reaction. The blood readily spreads under the cover glass and shows a marked rouleau formation.

The urine is characteristically negative and light with a low specific gravity.

At this stage, the asthmatic's nourishment is begun with first, whey, second, whey and toast, third, toast and lopped milk, fourth, lopped milk, cereals and vegetables, fifth, eggs and sixth, beef, lamb or fowl.

The asthmatic's food must be limited in quan-

tity so that he will not eat beyond his metabolic rate.

If the asthmatic eats beyond his metabolic rate, he will too greatly increase the viscosity of his blood which will often result in dyspnoea. This high-viscosity dyspnoea, if continued long, will disintegrate the asthmatic's unstable blood and result in a genuine attack of asthma.

In order to prevent these over-feeding, high viscosity, blood disintegrations, the asthmatic's blood and urine should be examined weekly and if the viscosity is too high, castor oil and mineral oil should be administered and a twenty-four hour starve period advised.

The asthmatic should return to the office of his family physician once a week for an examination during the first three months of treatment and once a month all of his life.

The examination of the urine and stool is of so much importance that the asthmatic is often furnished with charts and litmus paper and instructed in their use.

By modifying the lymph propulsion and exchange, aiding lung tissue in the performance of its glandular function, protecting the blood from hemolytic, meteoric-telluric phenomena and gases. While cleansing and correcting the chemistry of the blood as and when indicated, the prevention of asthma becomes a scientific and satisfactory procedure.

ADMINISTRATIVE IDEALS

When the President of the Medical Society of the State of New York assumes office, he finds a rich heritage of precedent on which to base his administrative policies and activities. The outstanding accomplishments of the last administration have been the passage of a Practice of Medicine Act, the establishment of an extensive system of graduate medical education, and the formation of a harmonious co-operation of the medical profession with the official departments of health and the great lay public health organizations. But each of these lines of work is only begun. Now that

the Practice of Medicine Act has been passed and signed, it must be put into operation, graduate education must be extended, new courses prepared, new teachers secured, and physicians must bestir themselves in popular medical education and disease prevention in order to do their proper share of the work in which lay organizations find their peculiar field. Carrying out these policies will afford the officers of the State Society abundant opportunity for the exercise of original thought and constructive building.

GEORGE M. FISHER,

PHYSICIANS IN MEDICAL LEGISLATION

How much influence do physicians have in medical legislation? Physicians may well pause and analyze the record of the Medical Society of the State of New York in its influence on legislation. The effort has been great and the motives sincere and the methods proper. Are the results commensurate with the effort?

The suggestion is frequently made that physicians should enter politics and get themselves elected to the legislature. Those who advocate this procedure believe that the best way to success in legislation is to adopt the methods of politicians, to form blocs and trade votes. No legislation of permanent value comes from this method, for it is based primarily on compromise and time serving, and is merely temporary in its results.

A note in the May 8 issue of the *Journal of the American Medical Association* states that one-fifth of the newly elected congress of Uruguay, South America, is composed of physicians, but that many of the doctors do not desire to serve and will not accept office. The doctors have the confidence of the people but they think they can serve the public best outside of legislative halls.

There is a deep psychological reason for the failure of physicians to guide legislation. The basis of American political popularity is service to others—the crude sort of service whose results may be immediately seen, such, for example, as securing a road appropriation for an impatient community. On the other hand nothing is more fatal to a politician's honor and success than obviously selfish motives, such as the charge that doctors are advocating a practice of medicine act because they are jealous of the illegal practitioners and are fighting to keep their patients. Doctors accomplish little when they say that they are working solely for the public good. Every selfish get-rich-quick schemer says that.

When Governor Smith held the hearing on the Practice of Medicine Bill on May 12, a big argument used by the hired counsel for the opposition was that the bill was sponsored by doctors for their own selfish protection. The Governor at once denounced this statement as false and said that the bill was sponsored by the two great State Departments of Education and of Health. The Governor might have added that he himself had strongly advocated a medical practice act in his annual message and that the natural persons to sponsor such an act were the two members of his cabinet who are chiefly concerned with medicine—the Commissioners of Education and of Health.

The essential factor in the passage of the Practice of Medicine Act was the demand for its enactment made by laymen. The great power of the opposition has always been that hundreds of

laymen have told legislators about their failure to get relief from doctors and their satisfaction with illegal healers. That those letters were inspired by the healers, has been well known, but it was Governor Smith who boldly stated that they did not represent the spontaneous desires of the petitioners, but that practically all the thousands of opposition letters which he received were almost identical in their wording, proving that they were inspired from a common source and were, therefore, not the demand of the people generally, but of a group of persons acting for their own selfish interests.

When doctors have introduced practice of medicine bills their letters, and the few notes written by their friends, have borne the same marks of instigation from one source and so were ineffective.

The great strength behind the enacted Practice of Medicine Bill was that of the lay public health organizations, particularly the tuberculosis committees which exists in every county. While the State Charities Aid Association is the State-wide body that has organized the county committees, yet each committee is run on the principle of home rule and is supported by the sale of Christmas seal stamps. The contributors and supporters of these committees are composed of from five to ten per cent of the population of the counties and state. When they spoke it was with influence and authority, and they upheld the Practice of Medicine Act with force and conviction.

What legislative influence then have physicians and their Medical Societies? Their influence is very great and essential. It appears in advice and education, given to the people of their own communities. If doctors have an influence, it will be apparent in the acts of their local friends. The legislators felt this influence, in a large amount for the first time when they heard from the members of the county committees on Tuberculosis and Public Health. These letters which were written, were individual and distinctive, and bore evidence of spontaneity on part of the writers.

The great influence of a doctor in private practice consists in advice, similarly the great power of the medical profession in legislation consists in the expression of advice and opinion.

Let the doctor express himself fully and clearly on legislative matters.

Let him assist the lawyers and heads of departments in writing medical parts of the bills, then let some one else introduce the bills and do the lobbying for them.

That is about the way the Practice of Medicine Act was passed, and its passage justifies the tactics of the Committee on Legislation.

NEW TEETH IN THE MEDICAL ACT

EDITOR'S NOTE This editorial from the New York *Herald-Tribune* of May 19, is an excellent interpretation of the Practice of Medicine Act which the Governor signed on May 17

From Governor Smith's memorandum on signing the Webb-Loomis bill, which amends the medical practice act, it appears that chiropractic and other cults may still practice their peculiar specialties so long as they do not trespass on the medical field. Their legal standing, if they may be said to have any, is not changed, but they cannot hold themselves out as "doctors" of any sort. That prohibition is valuable. What the spine thumpers and all their eccentric rivals want their patients to believe is that they are physicians, merely of a different school from the regular doctors. That deception is their great stock in trade. The use of the title "doctor," as Governor Smith says, "presupposes in the minds of a great many people a knowledge of the human anatomy sufficient to enable the holder of such title to diagnose and prescribe for all the ills the human body is heir to." The new law prevents the "doctor" pose by the panacea dealers. It is a decided point gained for public health.

The requirement of annual registration of all duly licensed physicians will enable the state to lay hands on the illegal practitioners, or at least assist in that salutary work. Guesses as to the number of quack doctors in the state run from 2,500 to 5,000. There has been no roll call of the medical profession in New York since 1880.

Some physicians have objected to the creation of a grievance committee which, in Governor Smith's phrase, will afford opportunity for the profession "to clean its own house." They have feared control by a group or "ring" within the profession. This disciplinary feature, however, is equivalent to the supervision exercised in the legal field by bar associations, and no more susceptible, it would seem, of abuse.

The medical practice act needed strengthening. The Legislature and the Governor are to be congratulated on their firm handling of a situation menacing to the people of the state.

LOOKING BACKWARD—THIS JOURNAL TWENTY-FIVE YEARS AGO

There is nothing new under the sun, not even in medical journalism. The founders of the NEW YORK STATE JOURNAL OF MEDICINE produced a highly creditable periodical and were always alert for new features. The JOURNAL for May, 1901, contains the following suggestion:

"Reports on The Sanitary Condition of Villages. It has been suggested by a member of the Standing Committee on Public Health of the State Association that the JOURNAL would be a good medium for the collection of facts in regard to the sanitary condition of the villages of the State. He says

"It is on the enforcement of preventable measures, then, that the solution of the question of the protection of a community for communicable diseases depends. But public laws and ordinances are most readily enforced which are most thoroughly endorsed by public sentiment, and a right public sentiment has its origin and development in an intelligent appreciation of the matter at issue. It is apparent, therefore, that the community which will most successfully protect itself against communicable diseases is that one whose individual members are most enlightened in regard to preventive measures. But who is to enlighten them? Evidently the local physician must be the instructor. It was the final instruc-

tions of Hippocrates to the graduates of the school at Cos that they should thoroughly study the sources of disease of the people in the locality where they practice, in order that they might most efficiently aid in the protection and promotion of the public health. Why should not the physicians of the State who are located in villages furnish the Committee on Public Health brief accounts of the sanitary conditions of their respective localities, with a view of having them collated and published in the JOURNAL for the information of the members of the association, and through them, of the people of the villages of the State? The facts thus accumulated would furnish the material for a most instructive annual report by the committee, which could be widely circulated among the people."

"The editor of the JOURNAL heartily approves of the above suggestions and will undertake to place in the hands of the Committee on Public Health any communications sent to his office of the character mentioned."

This idea seems to have died a-borning. We can readily understand why no doctor would dare to send an article describing the dirty dairy run by a local alderman, or the unsanitary tenement belonging to the mayor of his home town.

PHYSICIANS IN MEDICAL LEGISLATION

How much influence do physicians have in medical legislation? Physicians may well pause and analyze the record of the Medical Society of the State of New York in its influence on legislation. The effort has been great and the motives sincere and the methods proper. Are the results commensurate with the effort?

The suggestion is frequently made that physicians should enter politics and get themselves elected to the legislature. Those who advocate this procedure believe that the best way to success in legislation is to adopt the methods of politicians, to form blocs and trade votes. No legislation of permanent value comes from this method, for it is based primarily on compromise and time serving, and is merely temporary in its results.

A note in the May 8 issue of the *Journal of the American Medical Association* states that one-fifth of the newly elected congress of Uruguay, South America, is composed of physicians, but that many of the doctors do not desire to serve and will not accept office. The doctors have the confidence of the people but they think they can serve the public best outside of legislative halls.

There is a deep psychological reason for the failure of physicians to guide legislation. The basis of American political popularity is service to others—the crude sort of service whose results may be immediately seen, such, for example, as securing a road appropriation for an impatient community. On the other hand nothing is more fatal to a politician's honor and success than obviously selfish motives, such as the charge that doctors are advocating a practice of medicine act because they are jealous of the illegal practitioners and are fighting to keep their patients. Doctors accomplish little when they say that they are working solely for the public good. Every selfish get-rich-quick schemer says that.

When Governor Smith held the hearing on the Practice of Medicine Bill on May 12, a big argument used by the hired counsel for the opposition was that the bill was sponsored by doctors for their own selfish protection. The Governor at once denounced this statement as false and said that the bill was sponsored by the two great State Departments of Education and of Health. The Governor might have added that he himself had strongly advocated a medical practice act in his annual message and that the natural persons to sponsor such an act were the two members of his cabinet who are chiefly concerned with medicine—the Commissioners of Education and of Health.

The essential factor in the passage of the Practice of Medicine Act was the demand for its enactment made by laymen. The great power of the opposition has always been that hundreds of

laymen have told legislators about their failure to get relief from doctors and their satisfaction with illegal healers. That those letters were inspired by the healers, has been well known, but it was Governor Smith who boldly stated that they did not represent the spontaneous desires of the petitioners, but that practically all the thousands of opposition letters which he received were almost identical in their wording, proving that they were inspired from a common source and were, therefore, not the demand of the people generally, but of a group of persons acting for their own selfish interests.

When doctors have introduced practice of medicine bills their letters, and the few notes written by their friends, have borne the same marks of instigation from one source and so were ineffective.

The great strength behind the enacted Practice of Medicine Bill was that of the lay public health organizations, particularly the tuberculosis committees which exists in every county. While the State Charities Aid Association is the State-wide body that has organized the county committees, yet each committee is run on the principle of home rule and is supported by the sale of Christmas seal stamps. The contributors and supporters of these committees are composed of from five to ten per cent of the population of the counties and state. When they spoke it was with influence and authority, and they upheld the Practice of Medicine Act with force and conviction.

What legislative influence then have physicians and their Medical Societies? Their influence is very great and essential. It appears in advice and education, given to the people of their own communities. If doctors have an influence, it will be apparent in the acts of their local friends. The legislators felt this influence, in a large amount for the first time when they heard from the members of the county committees on Tuberculosis and Public Health. These letters which were written, were individual and distinctive, and bore evidence of spontaneity on part of the writers.

The great influence of a doctor in private practice consists in advice, similarly the great power of the medical profession in legislation consists in the expression of advice and opinion.

Let the doctor express himself fully and clearly on legislative matters.

Let him assist the lawyers and heads of departments in writing medical parts of the bills, then let some one else introduce the bills and do the lobbying for them.

That is about the way the Practice of Medicine Act was passed, and its passage justifies the tactics of the Committee on Legislation.

NEW TEETH IN THE MEDICAL ACT

EDITOR'S NOTE This editorial from the New York *Herald-Tribune* of May 19, is an excellent interpretation of the Practice of Medicine Act which the Governor signed on May 17

From Governor Smith's memorandum on signing the Webb-Loomis bill, which amends the medical practice act, it appears that chiropractic and other cults may still practice their peculiar specialties so long as they do not trespass on the medical field. Their legal standing, if they may be said to have any, is not changed, but they cannot hold themselves out as "doctors" of any sort. That prohibition is valuable. What the spine thumpers and all their eccentric rivals want their patients to believe is that they are physicians, merely of a different school from the regular doctors. That deception is their great stock in trade. The use of the title "doctor," as Governor Smith says, "presupposes in the minds of a great many people a knowledge of the human anatomy sufficient to enable the holder of such title to diagnose and prescribe for all the ills the human body is heir to." The new law prevents the "doctor" pose by the panacea dealers. It is a decided point gained for public health.

The requirement of annual registration of all duly licensed physicians will enable the state to lay hands on the illegal practitioners, or at least assist in that salutary work. Guesses as to the number of quack doctors in the state run from 2,500 to 5,000. There has been no roll call of the medical profession in New York since 1880.

Some physicians have objected to the creation of a grievance committee which, in Governor Smith's phrase, will afford opportunity for the profession "to clean its own house." They have feared control by a group or "ring" within the profession. This disciplinary feature, however, is equivalent to the supervision exercised in the legal field by bar associations, and no more susceptible, it would seem, of abuse.

The medical practice act needed strengthening. The Legislature and the Governor are to be congratulated on their firm handling of a situation menacing to the people of the state.

LOOKING BACKWARD—THIS JOURNAL TWENTY-FIVE YEARS AGO

"Reports on The Sanitary Condition of Villages. It has been suggested by a member of the Standing Committee on Public Health of the State Association that the JOURNAL would be a good medium for the collection of facts in regard to the sanitary condition of the villages of the State. He says

"It is on the enforcement of preventable measures, then, that the solution of the question of the protection of a community for communicable diseases depends. But public laws and ordinances are most readily enforced which are most thoroughly endorsed by public sentiment, and a right public sentiment has its origin and development in an intelligent appreciation of the matter at issue. It is apparent, therefore, that the community which will most successfully protect itself against communicable diseases is that one whose individual members are most enlightened in regard to preventive measures. But who is to enlighten them? Evidently the local physician must be the instructor. It was the final instruc-

tions of Hippocrates to the graduates of the school at Cos that they should thoroughly study the sources of disease of the people in the locality where they practice, in order that they might most efficiently aid in the protection and promotion of the public health. Why should not the physicians of the State who are located in villages furnish the Committee on Public Health brief accounts of the sanitary conditions of their respective localities, with a view of having them collated and published in the JOURNAL for the information of the members of the association, and through them, of the people of the villages of the State? The facts thus accumulated would furnish the material for a most instructive annual report by the committee, which could be widely circulated among the people."

"The editor of the JOURNAL heartily approves of the above suggestions and will undertake to place in the hands of the Committee on Public Health any communications sent to his office of the character mentioned."

This idea seems to have died a-borning. We can readily understand why no doctor would dare to send an article describing the dirty dairy run by a local alderman, or the unsanitary tenement belonging to the mayor of his home town.

MEDICAL PROGRESS

The Viruses of Epidemic Encephalitis and of Herpes—H Pette, of Hamburg, writes in the *Medizinische Klinik*, of April 9, 1926, regarding the relationship of these two viruses as demonstrated in animal experiments. Beginning with the use of the cerebrospinal fluid of encephalitis patients and the contents of the vesicles of human herpes simplex it was found some years ago that both of them produced a form of encephalitis in the rabbit, known from the first experimenter as "Kling's encephalitis." But this striking coincidence led to nothing definite, for clinically not the slightest analogy was found between the patient with encephalitis and the one who for any reason developed the vesicles of herpes simplex. On the contrary, further research only clouded matters. It was gradually learned that forms of encephalitis could be set up in rabbits which have been inoculated with the cerebrospinal fluid from a great variety of diseases—multiple sclerosis, tumors of the brain, cerebral syphilis, meningitis, pneumonia, influenza, etc. This line of effort was followed up by Flexner, of the Rockefeller Institute, New York. If one assumed that the cause of all of these laboratory diseases was an ultramicroscopic virus, then this organism must be ubiquitous. The author points out that in recent years there have been many reports from various parts of the world of spontaneous encephalitis in animals coincident with the outbreak of epidemic encephalitis in man. To come back to the subject of herpes there ought in theory to be a general infection of which the vesicles of herpes are merely an outward expression, but the only evidence that such a thing is possible is that of two cases of encephalitis in the rabbit following subdural injection of the cerebrospinal fluid of a patient with herpes. Despite the present confusion some increase in our knowledge may possibly come eventually from the data thus far obtained.

Herpes Genitalis—D von Pezold discusses this condition from the new viewpoint that the disease is infectious. There are two forms of herpes, simplex and zoster, and two forms of herpes simplex, facial and genital. The latter while in a sense trivial, may sometimes through its complications be burdensome, as when it causes inguinal adenopathy, or when it appears within the urethra. In such cases it may cause disability. It also may be very burdensome from its tendency to recur—at times almost continually. The author isolates what he terms a sexual type produced by men-

struation and orgasm, whether by coitus, masturbation or involuntary pollution. But in the constantly recurring type any trivial irritation, as an erection of the penis or ordinary uncleanness will precipitate an attack. Genital herpes shows a greater tendency to recur if the patient develops either gonorrhea or syphilis. It is only quite recently that the old neurogenic theory of herpes has given place to the doctrine of infection, based on the inconclusive fact that the contents of the vesicles are virulent when inoculated into small animals. While they may not reproduce herpes, they cause other lesions, and notably a form of encephalitis. Moreover this secretion contains so-called cell inclusions, which apparently indicate the presence of some ultramicroscopic organism, so that herpes simplex may be placed in the large group of infections which comprises herpes, zoster, molluscum contagiosum, venereal warts, trachoma, and even variola. The author distrusts the diagnosis of genital herpes and would always test the secretions for the treponema and Ducrey's bacillus and of testing the seroreaction of the blood for syphilis. In the treatment of relapsing herpes the most diverse remedies have been recommended—arsenic, small doses of potassium iodide, and yeast vitamin—even tomatoes, because of their content in water soluble B vitamin—*Deutsche medizinische Wochenschrift*, April 16, 1926.

Retraction of the Palmer Aponeurosis Associated with Dilatation of the Aorta.—Boulogne, writing in the *Bulletin Médical* of February 17-20, 1926, reports a case of the above coincidence. The patient, a man of 42, a mechanic, developed a retraction of the ring and little fingers symmetrical for both hands, these fingers being claw-like and distorted by a characteristic nodular aponeurotic cord, the index and medius being intact. There was no muscular atrophy in the forearms. This deformity had a traumatic origin going back to 1915, but the mechanism was obscure. The patient had been injured as a result of an automobile accident, but no lesions were apparent. There was a period of latency and the right hand was the first to show the deformity, the left soon following. The patient had always refused an operation. The author started with a theory of lupetic infection and although the Wassermann was doubtful gave the patient injections of arsenobenzol without any amelioration. A year or so after the development of the retraction the patient developed an intercostal neu-

ralgia found to be due to a right scoliosis at the level of the fourth and fifth dorsal vertebrae. The radiogram accidentally showed a dilatation of the aorta. The Wassermann was at this time clearly positive and the patient was placed on intravenous cacodylate of mercury but without changing the seroreaction. The ectasia of the aorta was unaccompanied by any clinical symptoms. The author believes that all three of the acquired malformations had a common origin and seeks to account for their interrelations. Could the dilated aorta have compressed the nerve roots, causing a trophic disturbance in the hands? This would hardly account for the scoliosis, unless this deformity had aided in making possible the compression. The roles of traumatism and syphilis are also obscure, but both may have figured in preparing the aorta for dilatation.

Toxemias and the Skin—Guillaume, in a long article in the *Bulletin Médical* of February 10-13, 1926, discusses the protective role of the skin in toxemias, simple and infectious. As is well known, the skin shows a peculiar reactivity in toxemias and bacilleurias, and this may be encountered as well when the processes are intraintestinal. This participation of the skin enters into the genesis of certain dermatoses which often improve notably after the alimentary canal has been evacuated. On the other hand the lesions are not favorably influenced by measures directed entirely toward the skin. In idiosyncrasies to drugs and food-articles, with outbreaks of wheals, etc., the cutaneous lesions resemble those produced by anaphylactic sensitization. In these cases a variety of measures may be useful and the toxigenic mechanism involved appears to be the vegetative nervous system, which has had its balance disturbed. It is well known that after severe burns a peculiar toxemia develops and the author associates this with the abolition of the antitoxic functions of the skin. In syphilis, when the disease expends itself on the cutaneomucous system, nervous accidents are very rare and unimportant because this system forms the natural defense against the treponema. The author now passes to surface immunity or allergic phenomena in which the immunisation of the skin is usually sufficient to protect the entire organism, as in smallpox vaccination and in the skin immunity which follows the syphilitic chancre, this being sufficient to render the skin immune to further inoculation. The diagnostic reactions of Schick, of Dick and of Pirquet and the analogous mallein reaction illustrate the same basic principle of immunity, showing that the latter exists naturally, just as certain forms of vaccination or inoculation immunity can be produced at will. In debilitated individuals the cutereactions seem

feeble in comparison with those in the robust. The author is not at all clear as to the interrelations between cutaneous and humoral immunity processes but evidently believes that the former must depend on the latter and these in turn on physicochemical processes.

Typhoid Bacillus Carriers—Hilgermann has for some time been treating typhoid carriers by means of sodium salicylate, given if necessary in massive doses. The idea is based on the fact that this salt, which is bactericidal to the typhoid germ, is eliminated partly in the bile. After the principle had been upheld by tests in vitro and animal experiment, the author began to employ it in human carriers with signal success, up to a certain limit, that is to say carriers could be sterilized and kept sterile over long periods, as long as they were taking the drug. The author mentions only sterilization of feces, saying nothing of the urine, although in the United States it is deemed necessary in all cases to sterilize the urine as well. When the drug is discontinued bacilli begin after a time to reappear in the stools. The author then passed to the treatment of animal typhoid caused by injecting the most virulent cultures into the peritoneal cavity of the guinea pig, with intravenous injection of the salicylate. The effects were striking, for some of the animals survived while the controls all succumbed. But some of the treated animals, although found sterile after death, died of a toxemia due apparently to the sudden lysis of a large number of bacilli and the release of the typhoid toxin. To control the latter the author combined his drug treatment with the use of typhoid antitoxin and was able to make a clean score of cures of the laboratory disease. He will in time report his experience in the treatment, along these lines, of human typhoid—*Muenchener medizinische Wochenschrift*, March 26, 1926.

Epidemic Angina Pectoris—Professor Hans Kohn discusses this subject in part from the historical angle. The term seems to have been used originally by Kleefeld who in 1823 reported an episode of the alleged affection in *Hufeland's Journal*. On examination this term seems to have been a misnomer for the condition described was clearly an infection, perhaps a grippe pneumonia. Late in the 50's Gelineau, who at the time was surgeon to the French warship "Embuscade," witnessed an epidemic form of angina which attacked some of the 250 members of the crew but the event was not reported until 1862. It was a period of sickness, the vessel being on a long cruise. In addition to the presence of scurvy, there were a number of cases of neuralgia and a condition formerly termed "colique végétale," with many synonyms, the English calling it dry belly-ache. Upon this substratum the symptoms of angina pectoris developed in 14 of the crew

At first Gelineau did not associate it with tobacco although when finally this thought occurred to him he espoused it warmly. He had associated the angina with the other neuralgias, while the colic was also regarded as of similar origin. At a somewhat later period the "colique végétale" was found by nosographers to be nothing more or less than plain lead colic and Kohn found that the French warships of that era abounded in lead construction. If we suppose that the 14 crew had lead colic the neuralgia of others could be similarly explained. If now we read the work of Tanquerel on lead angina pectoris we see how easily it fits into this episode. Finally we can explain the lead angina today as due to a spasm of the coronary arteries—one of the so-called "vascular crises" of Pal, who cites cases due to plumbism. Kohn exculpates tobacco as a factor, for every sailor uses this weed freely.—*Deutsche medizinische Wochenschrift*, March 12, 1926

Arteriosclerosis of the Cerebral Vessels and the Pathogenesis of Hypertension—Anrep and Starling, in a recent study, seem to have established as a definite physiological law a fact that has long been recognized by physiologists, namely, that a reduction in the amount of blood reaching the brain (presumably that part of it which has to do with vasomotor control) brings about a compensatory rise in the systemic arterial pressure. In consideration of this fact James Bordley, III, and B. M. Baker, Jr., (*Bulletin of the Johns Hopkins Hospital*, April 1, 1926, xxxviii, 4) investigated 24 cases of generalized arteriosclerosis, in 14 of which there was definite arterial hypertension, in order to determine if there were any contrasting anatomical conditions in the arterial supply of the medulla oblongata in these two types of cases. Arteriosclerosis was found without exception in the cases with a history of hypertension. In the cases with normal blood pressure the arterioles in this region were found unaltered. The authors feel justified in concluding that there is at least an association between persistent hypertension and arteriosclerosis of the vessels supplying the brain stem. In so far as it has long been recognized that arterial hypertension is accompanied by arteriosclerosis in at least some portion of the body, they suggest that a localization of this process in the medulla oblongata may be the essential factor in the production of persistent high blood pressure, although they recognize the objection that these changes may be secondary to the hypertension.

Palpable Arterial Coats in Children.—During the past year or two A. E. Vipond (*British Journal of Children's Diseases*, January-March, 1926, xxi, 265-267) has met with thickened arterial coats in a considerable number of children, and reports several illustrative cases. He finds that the condition is familiar,

and either the father or the mother will be found to have palpable arteries. The left ventricle is not hypertrophied, the blood pressure is normal or may be very slightly increased. If nephritis exists it is accidental, the condition is not connected with syphilis, scarlet fever, or any other disease. The condition is often discovered accidentally. Whenever a child is thin and below the normal size, it is well to look for palpable arterial coats. In fact the author makes a practice of examining the arterial coats of any child who is brought to him and is underweight and under size, and he frequently finds that the condition of arterial thickening exists.

Arsenical Treatment of Deafness—E. Wodak refers to a recent observation by Higier concerning two would-be suicides from arsenic who as a result of the poisoning recovered their long lost hearing. He had formerly pursued studies along this line and at once resumed them. Originally he had treated only otosclerosis and with injections, but now he made no distinction between the causes of deafness and gave arsenic by the mouth in the large dosage which obtains in pernicious anemia—from 30 to 50 mgms of arsenate of sodium daily in pill form. It is of course possible to go even higher but while the dosage was on the whole well borne some of the patients suffered from digestive disturbances of a burdensome character. When tolerated the treatment was kept up until between 200 and 300 mgms had been taken all told, after which the patient was given several months rest. The author has now treated 166 deaf subjects with all forms of deafness—otosclerosis, chronic otitis media, cochlear neuritis and senile deafness. All of these forms have been benefited and no one form seems more or less amenable to treatment than another. In the best results the patient hears 10 fold more or better than before treatment and in the least favorable twice as well. In about a third of all cases however results will be negative and of his 166 some 62 failed to obtain any relief. Ten obtained the highest grade of relief, 16 the next highest, 35 the third highest while 43 obtained the least benefit although doubling their hearing power. Of the 166 patients 100 suffered from chronic otitis media and its sequelæ, 32 with otosclerosis, 17 with cochlear neuritis and 8 with senile deafness. *Deutsche medizinische Wochenschrift*, March 26, 1926.

Cholesterol Metabolism and Hair Growth—Rud. Jaffe mentions the belief that the normal stimulation of hair growth is due to the cholesterol content of the sebaceous glands, so that conceivably an excess of this substance in the blood with increase of elimination favors hair growth just as a lowered content results in shedding of the hair. This view is borne out by

certain facts as in the case of pregnant women who show a luxurious hair growth but after delivery begin to lose hair rapidly. Here the hypercholesterinemia of gestation, associated with and dependent upon cessation of elimination of the substance by the bile, is followed by a great reduction due to resumption of such elimination. It occurred to Jaffé that if chloesterol were rubbed into the skin and later eliminated with the sebum the hair would get the benefit of the reinforcement of the ordinary amount. He then conducted experiments on rabbits, using controls, in which large surfaces were denuded of hair by depilatories. Into some of these patches he rubbed cholesterol in ointment form, of 50 per cent strength, some ointments being pure while others contained some tarry substance. When these areas were contracted with others in which nounctions had been made it could readily be seen that islets of hair growth were forming in the denuded skin, about four weeks being required for the purpose. There was also a deposit of pigment in these islets. Comparing the total results it was evident enough that the cholesterol and not the tar was to be credited with the positive result. The author is to write a sequel on the clinical use of the remedy in man—*Klumsche Wochenschrift*, March 19, 1926.

The Use of Non-Specific Foreign Protein in the Treatment of Inflammatory Lesions of the Female Pelvic Organs—Since 1923, A. D. Campbell (*The Canadian Medical Association Journal*, April, 1926, xvi, 4) has treated 300 cases in both hospital and private practice with protein injections. Of these he has analyzed and tabulated the first 100 completed cases. The earlier trials were restricted to patients in whom inflammatory disease had converted the pelvic viscera into a painful mass. Later, however, the treatment was extended to include gonorrheal infections, acute or chronic, as well as infections of uncertain types following abortion, parturition, curettage, etc. The technique consisted in the use of commercial milk sterilized in a water-bath for ten minutes, the usual aseptic precautions being taken. The site of the injection was in the area below the crest of the ilium in the mid-axillary line, because here the superior gluteal nerve is the only one possible to be injured, while in the gluteal region the nerve supply is more abundant. The initial dose is 4 c.c. subsequently increased to 6 to 10 c.c. One injection every five days apparently gives the best results, though the intervals may vary

from four to seven days. The general reaction begins in from 45 to 90 minutes and the temperature may reach from 101° to 104° in six to eight hours, rigors rarely occur and vomiting still more rarely, though headache is an almost constant symptom. The acute cases showed 55 per cent of cures, with nine weeks of treatment, while the chronic cases showed only 18 per cent of cures, and this in spite of twelve weeks' treatment. With infections involving the higher portions of the tract, whether salpingitis or tubo-ovarian infection, with so-called pelvic peritonitis, the results were about the same in each group, namely, 44 per cent cured, 40 per cent improved, 16 per cent no change, except that tubal infections not involving the ovary required twelve weeks' treatment as against nine weeks where there was no tubo-ovarian mass. In the chronic types of cases the treatment proved distinctly disappointing, giving only about 20 per cent of cures.

A New Application for Varicose Ulcers—Robert H. Davis (*Archives of Dermatology and Syphilology*, April, 1926, xiii, 4), at the suggestion of F. P. Dunnington who thought it would be a stimulating and antiseptic application for ulcers and an excellent antiseptic remedy for small abrasions, tried a formula consisting of boracic acid 63 gm., potassium hydroxide (stick) 28 gm., and water 200 c.c. in 55 cases of varicose and traumatic ulcers. The lotion is prepared by heating the boracic acid and potassium hydroxide with 150 c.c. of water in a porcelain dish, allowing it to cool, and then filling it to 200 c.c., giving a solution with a specific gravity of 1.2. In only one of the 55 cases was there complete failure to respond to the treatment. The solution, while mild in action on the unbroken skin, is frequently painful if used in full strength on ulcers. It appears to be best to begin the treatment by using the solution in one-half strength, increasing tentatively to full strength if the pain is not too great. Some of the chronic indolent cases did not respond until full strength was used, but the majority of the patients did well with a lesser concentration. If possible, the application should be made tri-weekly at least. An elastic webbing bandage for severe varicosities was used during the day in a few instances. Davis has used this treatment for two and a half years on all varicose and traumatic ulcers coming to his department, and feels that it is at least an additional valuable method in combating this often stubborn condition.

LEGAL

By LLOYD PAUL STRYKER, Esq
Counsel, Medical Society of the State of New York

THE WEBB-LOOMIS BILL BECOMES A LAW

The 17th day of May, 1926, will stand out as an important date in the history of the public health in New York State. On that day the Webb-Loomis Bill was signed by Governor Smith and became a law. It is now a part of the statutes of this state as the bill provides that "This act shall take effect immediately." From now on it will be known as Chapter 834 of the Laws of 1926.

This measure has had a stormy career. Its passage never would have been secured but for the conscientious, able, indefatigable and intelligent sponsorship of the doctors of this state, who place the safeguarding of the public health as the highest aim of the profession. The bill was drafted by a Committee of the Medical Society of the State of New York appointed by President Nathan B. Van Etten in pursuance of a resolution adopted at the annual meeting of the House of Delegates held in Syracuse in May, 1925. The Committee consisted of Dr. John E. Jennings, Dr. George M. Fisher, Dr. Thomas C. Chalmers, Dr. George A. Leitner, Dr. James E. Sadler, Dr. George B. Stanwix and Dr. Frederick H. Flaherty. With a disregard of the inevitable inroads upon their time, their leisure and their strength, these gentlemen sat together for many weeks and with a patience, an open-mindedness and a public spirit which is beyond praise, after hours of debate, of research, of study and a mutual exchange of views, designed, prepared and wrote the measure which has now received the sanction of the chief executive of this state. Conferences, of course, were held with the Departments of Health, of Education and with the office of the Attorney-General, differences and inconsistencies were reconciled, constitutional and administrative objections were eliminated, so that when the bill was finally introduced into the lower chamber by Assemblyman Loomis and into the higher body by Senator Webb, the measure expressed not only the best opinion of the medical profession, but of the public health authorities, upon whom so largely will devolve the duty of administering it.

This law was written by the hand of man and nothing which comes from that source is perfect. Therefore, the proponents and advocates of this bill will not claim perfection for their work. What is claimed, however, and what cannot be disputed is, that the new Medical Practice Act is the best law of its kind which has ever been written into the statutes of our state and that it

marks an advance in the safeguarding of the public health and the regulation of the medical profession which entitles it to become a model for similar enactments in other states of the Union.

No statement concerning the new law would be complete which did not render just praise to the splendid public efforts put forth by Dr. Henry L. K. Shaw, the chairman, and Dr. Arthur W. Booth and Dr. Clarence F. Graham, the members of the Legislative Committee of our State Society, in securing its adoption. From the writer's own personal contact with these public-spirited physicians he can testify to the fine spirit, the intelligent attitude and the courageous and optimistic leadership which these true friends of the medical profession brought to bear upon the difficult, harassing and oftentimes discouraging task which they so cheerfully assumed and now have brought to a successful conclusion. Also mention should be made of the indefatigable, effective and loyal efforts put forth by Dr. Joseph S. Lawrence, the Executive Officer of the State Society.

It is needless at this time to review the various provisions of the bill, as they have long since become familiar both to the proponents and the opposers of the measure. A full discussion of its essential provisions was set forth in our editorial in this JOURNAL of March 15, 1926.

Never has a bill enlisted a more active propaganda or a more highly organized and skillful opposition from the cultists, who have spared nothing of time or money to thwart and defeat this new safeguard of the public health—men who insolently boast of the magnitude of the returns which they derive from their unlawful practice. The chiropractors and other criminals and their dupes have seen this measure coming home and prepared to oppose and to defeat it. But they have failed.

As early as the fall of 1924 Governor Smith called a conference of representatives of the State Department of Health, the State Medical Society and the State Department of Education for the purpose of considering amendments to the Medical Practice Act. In his annual message to the Legislature in 1925 the Governor called special attention to the necessity of enacting legislation which would rid this state of illegal practitioners of medicine in the interest of the public health. Thereafter a bill was prepared by the Department of Education and introduced in the legislature embodying the fundamental principles

agreed upon at the conference. That bill was supported by the State Department of Health, the State Department of Education and the State Medical Society. It passed the Assembly by an overwhelming vote, but failed in the Senate in spite of the fact that on the very last day of the session the Governor sent a strong special message urging its enactment.

"The situation," wrote Governor Smith in his memorandum accompanying his signature of the Webb-Loomis Bill, "now as at that time demands remedial legislation. Attempts made in the past have failed for one reason or another, notwithstanding the fact that it could not by any stretch of the imagination be made either a political or a partisan matter, as it concerns only the health and lives of the people of the State." "In 1926," Governor Smith continues, "I reviewed the recommendation of a year ago and recommended that legislation be enacted in order to protect the people of the State from unlicensed and unqualified persons practicing medicine. As a result of such recommendations, I have before me what has come to be known as the Webb-Loomis Bill. * * * It does provide for a better administration of the Medical Practice Act and is solely in the interest of the preservation of the health and lives of the people of our commonwealth."

The bill does not change the definition of the practice of medicine contained in Section 160 of the Public Health Law and which has been in effect for nearly twenty years. In that section the practice of medicine is defined as follows:

"A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake, by any means or method to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition."

This definition has been frequently before the courts and has been uniformly upheld. For nearly twenty years any person not duly authorized to practice medicine within this state, but who nevertheless has done any or all of the things specified in this section, has been guilty of a misdemeanor punishable by a fine of not more than five hundred dollars or imprisonment for not more than one year or both.

Under this law it has been repeatedly decided by the courts that a chiropractor not licensed to practice medicine who in anywise diagnoses, treats or prescribes for human ailments is guilty of a crime. The leading case on that subject is *Peo v Ellis*, 162 App Div 288, decided in 1914, and there are other cases upholding the same doctrine, among which are *Peo v Mulford*, 148 App Div 716, *Peo v Somme*, 120 App Div 20, *Peo v Allcutt*, 117 App Div 546.

As recently as February 24th of this year the Court of Appeals, in considering the treatment of a chiropractor declared

"The defendant had no license to practice medicine, yet he held himself out as being able to diagnose and treat disease, and under the provisions of the Public Health Law (Cons Laws, ch 45) he was guilty of a misdemeanor."

The chiropractors, with a brazenness unparalleled in the history of quackery, admit that the law is as the writer has just defined it and that they violate it. This admission was frankly made by Judge Vanderzee, the general counsel of the New York State Chiropractic Association, at one of the hearings before the Joint Public Health Committee of the Assembly and the Senate, and again in the Executive chamber, before Governor Smith at the hearing which he called on the evening of May 12th of this year, when he frankly conceded that the chiropractor who carries on his so-called profession, but who is not licensed to practice medicine, is a lawbreaker. The argument put forth by this counsel for admitted law breakers was that the Webb-Loomis Bill should not be signed because it increased the penalties for lawbreaking. When the Governor pressed Judge Vanderzee on this point, the counsel for the chiropractors was unable to give a satisfactory answer.

Let there be then no confusion on this point. The new law does not and was not designed or intended to make unlawful that which was lawful before. It was not designed or intended even to increase the penalties for lawbreaking. What it was designed and intended to do and what it does is to provide a stronger and more effective instrument for the prosecution of those who defy, flout and break the criminal law of this state prohibiting the practice of medicine on the part of those who are not qualified and legally authorized to practice it. This is what Governor Smith meant when he said

"Although no cult is licensed to practice in this State, it does not stop the practitioner of such cult from practicing the tenets of that cult by any manipulations or any other form of treatment, *provided such practice does not involve a violation of the Medical Practice Act or any other section of the Public Health Law as it existed before the enactment of this bill*."

But the practice of chiropractic does involve and always has involved a violation of the Public Health Law of this state—a fact attested by the cases we have cited and by the plain admission of the counsel for the chiropractors. In other words, the new law does not make the practice of chiropractic unlawful, because that practice already was unlawful before the enactment of this new measure and the illegality of that practice is not made more or less illegal by reason of the statute just enacted. The argument of the chiro-

practitioners, the drugless healers and other violators of the criminal law was therefore, a novel and fantastic one, it was an argument against making more effective the prosecution of their acts which they admit are criminal. This argument was justly spurned by Governor Smith. His answer to it was the signing of the bill.

Governor Smith's memorandum which accompanied his signature is a model of clear statement. This fine public servant deserves and has received the warm commendation of the doctors and of all others who are laboring to safeguard the public health. In referring to the annual registration requirement the Governor thus expressed himself:

"It requires very little explanation to show the necessity for this very wise regulation. Prior to the enactment of the Dental Law, thousands of unlicensed practitioners were practicing dentistry in this State. Some of them were unfit to practice on lead pipe, not to speak of experimenting with human beings. The annual registration of dentists threw the illegal practitioners out of the State, thereby giving to the people of our State a protection against fraud that they could get in no other way. The Department of Education records show that its ten years of experience in the administration of the Dental Practice Act and other acts relating to the professions, has demonstrated that annual registration is the most effective agency for freeing the State from imposters and illegal practitioners and of keeping it free from such violators of the law."

As time goes on we are confident that those members of the medical profession who have opposed annual registration will appreciate the justice of the Governor's observations. The burden which it entails, upon experience will be found to be negligible. We quote from our editorial of March 15th:

"The secretary of the board of medical examiners must mail, on or before October 1 of each year, to each registered physician a blank form of application for registration. The physician then has three months in which to make out this registration and send his check for \$2.00. The burden thus entailed from the financial point of view, of course, is negligible, and from the standpoint of annoyance or inconvenience it is reckoned that it will not consume more than three minutes of the doctor's time once each year. As compared with the provisions of the law requiring registration for voting, annual registration of automobiles and the innumerable other provisions which in our complicated system are now required of all citizens, this requirement for annual registration is negligible. Its value should be apparent to every one. Its purpose is not only to provide the sinews with which to enforce the public health law, but to provide and keep up to date an authorized list of licensed physicians."

In regard to the provisions of the bill requiring that prosecutions for its violation shall be conducted by the attorney-general, except in counties having a population of more than 500,000, in which the law expressly declares that "nothing in this section shall be interpreted to prevent or impede the prosecution of such proceedings by the district attorney * * * when such proceedings shall have been initiated by him," the Governor said:

"The reason for this is obvious. A violation of the Public Health Law is not a violation against a county or any other subdivision of the State. It is against all of the people of the State. A careless administration of the Public Health Law in a given locality not only endangers the lives of the people of that locality but of all the people who come in contact with them. Public health work by its very nature must be statewide to be effective."

As to the physio-therapy provisions of the law which require that "A license to practice physio-therapy shall not permit the holder thereof to administer drugs or to practice medicine as defined in section one hundred and sixty of this article, except to treat diseases under the supervision of a duly licensed physician," the Governor said:

"It will afford treatment of the sick and ailing by properly trained physiotherapists *working under the direction of duly qualified physicians*. This provision enlarges the field of treatment without the dangers incident to treatment by untrained and unqualified practitioners."

But nowhere in his memorandum does Governor Smith more clearly reveal his fine appreciation of the dignity and importance of the medical profession than in his discussion of the time-honored and jealously-guarded title of "doctor." Under the new law:

"Any person who * * * shall * * * Use the title 'doctor' or any abbreviation thereof in connection with his name or with any trade name in the conduct of any occupation or profession involving or pertaining to the public health or the diagnosis or treatment of any human disease, pain, injury, deformity, or physical condition, unless duly authorized by law to use the same, * * * shall be guilty of a misdemeanor."

No chiropractor or other unlicensed individual is authorized to use that title. Concerning the provisions protesting that time-honored title the Governor declared:

"It will protect the public from the exploitations of quacks and charlatans by regulating the use of the title 'doctor' and by the prevention of fraudulent and deceptive advertising. I regard it as highly important that the ignorant and unthinking be not misguided by the use of the title 'Doctor' because it presupposes in the minds of a

great many people a knowledge of the human anatomy sufficient to enable the holder of such title to diagnose and prescribe for all the ills the human body is heir to. The title 'Doctor' should be made by law to mean what the great majority of people believes it means, and it should not be promiscuously bestowed upon individuals so lacking in proper qualification as to be unable to tell the difference between indigestion and hydrophobia. There is no function of government to my mind more important than the preservation of the public health."

Is it any wonder that chiropractors, drugless healers and others who in disregard of law and common decency have fraudulently attached the title "doctor" to their names, who have organized an opposition to the Webb-Lomis Bill, and who have written thousands of letters to the Governor opposing it, should have come to the Executive chamber with a large following to urge the Governor's exercise of his veto power?

The enactment of the Webb-Loomis Bill marks an epoch in the history of the public health. Let us go forward under it with a determination to carry out its provisions so as to give full effect both to their letter and to their spirit. Never before has the Medical Society of the State of New York given greater vitality to the purpose for which, six score years ago, the Society was organized. Under the leadership of President Van Etten, President Fisher and Chairman Henry L. K. Shaw, the purposes of the Society as defined by the first article of its Constitution have been given a new life. Among those purposes are these

"* * * to extend medical knowledge and advance medical science, to elevate the standard of medical education, to secure the enactment and enforcement of just medical laws, * * * and to enlighten and direct public opinion in regard to the great problems of medicine."

INFECTION OF FINGER

In this action it was charged that the defendant was engaged to treat the plaintiff for a blister on the right hand, that he advised that it was necessary to operate upon the hand, and in doing so was careless and negligent, causing plaintiff's hand to become infected and the loss of use of the index finger and that plaintiff was likewise required to expend money for other medical attendance and nursing and was prevented for a long period of time from attending to a usual business of operating a restaurant.

When the defendant first saw this patient she gave a history of having several days prior lacerated her index finger and of having received several treatments at a White Cross Emergency Station, from which she received no benefit. Upon examination the defendant found the finger stiff and swollen and evidences of considerable pus. He advised an immediate incision to provide proper drainage and further advised her that if this procedure was not followed there was danger of the infection spreading to the hand and arm.

The patient consenting, the finger was incised and a quantity of pus drained therefrom. A sterile drain was placed in the wound, the finger dressed and the patient instructed to return on the following day. The next day, upon the patient's return to the defendant, she stated that she

was greatly relieved and had had the first night's sleep since the injury to her finger. Upon removing the dressings the physician found a little excessive bleeding at the upper corner of the incision. A suture was inserted which controlled the bleeding, the wound sterilized and dressed and the patient instructed to return the next day. For three successive days the patient returned to the defendant, at each of which times the dressing was removed, the wound cleansed and the finger rebandaged, the injury showing marked improvement at each of the visits. At the last of these visits the improvements was so marked that the defendant advised the patient not to return unless the finger gave her further trouble. This was the last that the defendant saw of this patient. The defendant's nurse, however, met the plaintiff on the street, at which time the plaintiff told the nurse that her finger was stiff and she did not believe that the doctor had given the proper treatment to her injury.

Shortly thereafter this action of alleged malpractice was instituted against this physician. The attempts upon the part of the plaintiff's attorney to procure a compromise or settlement met with no avail and the action was dismissed when the same was reached for trial thus favorably terminating the action in favor of the defendant.

MEDICAL SURVEY

STATE CARE OF PATIENTS MENTALLY SICK

Governor Alfred E. Smith has authorized the publication of a large illustrated pamphlet describing the expenditure of the proceeds of the fifty million dollar bond issue which was authorized at the General Election of 1923 for the State care of the sick in State institutions. Most of these patients have mental disorders, and so the object of the bond issue is popularly stated to be the care of the insane and the mentally defectives.

The burden of the wise expenditure of the bond issue falls on the physicians of New York State, and every doctor is therefore deeply interested in its hospital system. The object of this survey is to give a bird's eye view of the State Hospitals, the policies under which they are conducted, and the plans for modernizing the buildings and equipment, and the management of the patients. The survey is written from the standpoint of the physician in general practice, and will give the information which the family doctor can impart to the families of his mental cases.

People generally are ten or twenty years behind the medical leaders in their knowledge of diseases and treatments, or, to state the fact in another way, it takes ten or twenty years for a knowledge of new discoveries and medical standards to be understood and accepted by laymen. The people are a generation behind the times in their knowledge of what can be done for the mentally sick, and physicians usually have great difficulty in getting the patients and their families to accept the diagnosis of mental trouble that is plainly evident to the doctors. The popular opinion of a mental disorder is that it is a disgrace which is to be concealed as long as possible. The opinion is similar to that regarding tuberculosis twenty-five years ago. Physicians have the opportunity to change that opinion, just as they have educated the people regarding tuberculosis.

History sheds light on the popular attitude toward mental disorders. The views of the scientific leaders have developed in five stages.

1 The people of ancient times believed that an insane person was inspired by the gods, and that his actions showed that he was conversing with unseen spirits. His words, though often mysterious and unintelligible, were sometimes the fearless expression of truth whose utterance would cost a sane man his life. While this idea persisted, the church took care of the insane on the basis of their sanctity. Many

of the hermits of the Middle Ages belonged to this class.

2 The second stage of belief was that the insane were possessed of the Devil—the exact opposite of the first belief. Many of the miracles of Christ consisted in “casting out devils” from the insane, and that expression is used frequently in the New Testament. This view was the basis for the belief in witchcraft, and it still persists among the Negroes, and is present in a subconscious form among otherwise educated folk who should know better. The logical outcome of this belief was the imprisonment and execution of the insane in the belief that they menaced society.

3 The third stage of the development of the care of the insane was a softening of the implacable attitude of society, but the retention of the idea that the insane were criminals. One hundred years ago it was a legal crime to be insane, and the punishment was close confinement in irons, the same as that meted out to dangerous criminals. Jails and almshouses harbored the chained insane for whom no one seemed to have a care and whose recovery was wellnigh impossible.

4 The fourth stage was the assumption of the care of the insane by the poor-house authorities. Almshouses were fitted with padded cells in which the insane were placed in solitary confinement, which was almost as depressing as incarceration in public jails. The most that was expected from care in the poorhouses was that the patients would be given the bare necessities of life until death mercifully ended their sufferings. Yet the legal status of a mental patient was still that of a criminal.

5 The fifth stage was the recognition of insanity as a mental problem which the State alone could solve. The care of the insane by towns and counties offered little hope of success, the State alone had the resources to assemble a sufficient number of patients in one place to justify the preparation and equipment of hospitals, and the employment of specialists in mental diseases. It was not until 1890 that New York State assumed the responsibility for the care of all the insane. Let those who criticize the slowness of State officials in acting for the relief of the insane consider the fact that full provision for the care of cases of tuberculosis has not yet been made.

This history of the development of the care of the insane is revealed in the descriptive names successively applied to an institution for their

care—madhouse, poor-house, asylum, and hospital. All the institutions have been called hospitals for a decade or more, and yet many physicians still call them asylums, and the people generally call them "madhouses" or "bug" houses. Here it may be stated that the word "bug" as applied to insanity is good English. Thus, Sir Thomas More, in 1573, wrote "Lest there hap to be such black bugs indeed as folks call devils, whose torments he was wont to take for poets' tales." Bug then meant a terrifying specter, and that is what a buzzing "June bug" still is to many persons.

The persistence in the old belief regarding the State hospitals is a great handicap to doctors in their care of the insane. Old tales of the horrors of madhouses, and of the cold monotony of asylums still persist, even among educated people. The power of tradition, and the influence of childhood's tales on subconscious beliefs are more powerful and dominating than the few descriptions of modern State hospitals that have reached the people. The education of people in the principles of insanity, mental deficiency, and mental hygiene is one of the great lines of public health work in which physicians are naturally the leaders.

The State had made experiments in the care of the insane previous to 1890 when it established the policy of the care of all the insane. The honor of leadership in the modern system of State care belongs to the Medical Society of the County of Oneida which, as early as 1840, began the agitation for a State hospital for the insane which resulted in the establishment of the Utica State Hospital in 1843. The Utica institution was designed for the care of acute cases which were recognized as curable, and were transferred to it from the county almshouses. The next State hospital to be established was the Willard State Hospital at Willard, Seneca County, in 1869, for the care of the chronic cases. From these small beginnings has come the present system consisting of fourteen hospitals already in operation, and also two for the criminal insane.

There are also 28 private hospitals licensed to receive insane cases. Their capacity varies from 3 to 270, and the total number of beds is about 1,500. Only five of the private institutions have capacities of over 100 each.

The thirty-six years that have elapsed since the adoption of State care for the insane have seen great advances in the knowledge of the nature of mental disorders and in the methods of treatment. What was obscure a generation or two ago is now plainly evident. Diseases of the mind, like those of the heart, are now recognizable in their early stages while they are curable, and to enter a mental hospital is no longer a life sentence.

TABLE I

Table of State Hospitals for the Care of the Insane

Name	Location	Year of Establishment	Normal Capacity	Number of Cases on Jan. 1, 1926
1 Utica State Hospital, Utica		1843	1,279	1,924
2 Willard State Hospital, Willard, Seneca Co		1869	2,091	2,669
3 Hudson River State Hospital, Poughkeepsie		1871	3,338	4,136
4 Middletown State Homeopathic Hospital, Middletown		1874	2,135	2,580
5 Buffalo State Hospital, Buffalo		1880	1,866	2,478
6 Binghamton State Hospital, Binghamton		1881	2,383	2,886
7 St. Lawrence State Hospital, Ogdensburg		1890	1,621	2,373
8 Rochester State Hospital, Rochester		1891	1,298	1,995
9 Brooklyn State Hospital, Brooklyn		1895	1,033	1,822
10 Central Islip State Hospital, Central Islip		1896	4,248	6,031
11 Kings Park State Hospital, Kings Park		1896	3,471	5,401
12 Gowanda State Homeopathic Hospital, Helmuth, Erie Co		1898	859	1,405
13 Manhattan State Hospital, Wards Island, N. Y. C.		1905	4,847	7,125
14 Harlem Valley State Hospital, Wingdale, Dutchess County		1924	300	272
15 Dannemora State Hospital, Dannemora, Clinton County		1896	538	571
16 Matteawan State Hospital, Beacon Dutchess Co		1892	657	975
TOTAL			30,769	44,643

Slowly, a correct attitude is being developed toward accepting treatment, and patients are beginning to go to the hospitals voluntarily for examination and treatment just as they go to tuberculosis hospitals for incipient infection, and to general hospitals for pneumonia or appendicitis. This approaches the ideal state of mind toward the State hospitals.

The existing hospitals are the results of evolution from small beginnings, when the principal object was to provide asylums for detention rather than hospitals for treatment and cure. When a hospital became overcrowded, additional buildings were erected, and the old ones retained, but construction has never kept pace with the over-crowding, even according to asylum standards, until now the hospitals have 28 per cent more patients than they were designed for, and the crowding would be even worse except for the fact that patients are often discharged long before their progress is considered likely to be permanent. Not only should patients be admitted to the hospitals in earlier stages of sickness, but they should be kept there for longer periods, and not be turned out in a stage when their return is fairly certain.

Much has been written about the great increase in the numbers of the insane. The question arises—is the increase due to a greater proportion of the people becoming insane? or is it due to the increasing number who accept early treat-

ment and are eventually cured? No matter how the question is answered, all agree that the peak of numbers who would be benefitted by State hospital care has not been reached, and that more beds are urgently needed, and will be needed throughout the present generation of time.

The previous system of construction has not only produced buildings unsuited to modern standards of treatment, but it has also prevented the development of a scientific organization of the medical staff. Efficiency of treatment requires that the physicians be organized in groups or services, each with complete medical facilities for making complete examinations, physical as well as mental, and for giving all forms of common treatments. Moreover, comfortable living quarters for the doctors, nurses, and attendants are necessary in order that those in charge of the patients may render the best service. The requirements of the medical service are well set forth in a pamphlet by a committee headed by Dr. George H. Kirby, Director of the Psychiatric Institute of the New York State Hospitals. The committee made a report on October, 1924, and made fifteen recommendations on the following topics, which apply to each hospital:

- 1 A reception service for receiving and studying new cases
- 2 A diagnostic clinic
- 3 A service for the treatment of general medical and surgical conditions
- 4 Improved nursing service
- 5 An increased number of physicians per patient. At least one physician is required to

9 The performance of central staff duties by the personnel of each service

10 Each medical service to be a unit in keeping records

11 Unified dental service

12 Staff meetings in general medicine as well as in mental diseases

13 Liberal appropriations for medical and surgical supplies, including medical books

14 The development of social service work in following up paroled cases

15 The standardization of methods for all services whereby the best of each may be adopted by all. The committee, however, recognizes the difficulty of accomplishing this ideal in the present buildings.

These recommendations are not idealistic. They are made by a committee of practical men who have seen the features already introduced into several hospitals, no one of which has been able to adopt even a majority of them on account of the physical limitations of the buildings. To change the buildings and increase their capacity will cost money which will be supplied by the fifty million dollar bond issue.

MENTAL DEFECTIVES

In addition to the insane, the State cares for its mental defectives. It is estimated that New York State has 50,000 mental defectives who require supervision, and that 10,000 of them are unsocial to such an extent that they require treatment and restraint in public institutions. The State now maintains four large institutions for the reception and care of mental defectives, as will be seen from the accompanying table.

TABLE II
State Schools for Mental Defectives

NAME	LOCATION	Year of Opening	Normal Capacity	No of Inmate, July 1, 1925
Syracuse	Syracuse	1854	700	627
Rome	Rome, Oneida County		1,350	1,607
Newark	Newark, Wayne County	1878	900	1,126
Letchworth Village	Thiells, Rockland County	1911	1,700	1,837
TOTALS			4,650	5,197
On parole				958
In colonies outside of schools				1,060
Total mental defectives under State care				7,215

every 150 cases, but some doctors are trying to care for 1,000 cases.

6 More visiting specialists in internal medicine, surgery, urology, orthopedics, gynecology, and so on through the whole list.

7 A clinical director of all medical services and the helpers in them.

8 Standardization of the medical equipment for each service.

The care of mental defectives has undergone an evolution similar to that of the insane. The immediate problem in construction in each instance has been to provide an asylum for the segregation of a particular kind of case. The first institution to be established was a small one in Albany which was started in 1851. It was transferred to Syracuse three years later, and is now maintained as one of the large institutions of the State.

The State institutions for mental defectives were under the supervision of the State Board of Charities until the year 1919, when the State Commission for Mental Defectives was established. This Commission was given duties and powers which were largely similar to those of the Hospital Commission which controls the hospitals for the insane.

The present policy of the State is to develop each institution into an all-around school in which all kinds of cases will be taken, as in the State hospitals for the insane. While the care of mental defectives is a medical problem similar to that of the care of the insane, yet between the two types of institutions there is a real distinction which is expressed by the word "school" in relation to mental defectives and hospitals in relation to the insane. Each institution for mental defectives is called a State School for Mental Defectives, preceded by the name of the place in which it is located. Thus, the title of the School in Newark is the Newark State School for Mental Defectives. However, the one in Rockland County is still called Letchworth Village.

Each State School for Mental Defectives will receive cases of all kinds, degrees and ages. Each is a school in fact, in which the inmates are taught useful trades, and prepared to take positions as household workers, farmers, and mill operatives. When they are sufficiently skilled, they are paroled under the care of competent persons. The Syracuse School accepts only those who are capable of responding to training, but the others accept incurable cases also.

A system of colonies of the inmates designed by Dr. Bernstein, Superintendent of the Rome State School, is in operation in connection with several of the schools. The plan is that a group of from ten to twenty inmates shall be lodged in a house in an industrial center, and from which they shall go out to work for hire. The wages which they earn is credited to the inmates as a saving bank account which is donated to them by the State. The Rome State School has 32 such colonies at which the boys and girls live normal lives and have the self-respect which goes with the ability to earn money for themselves.

The building program for the care of mental defectives consists of the establishment of a new institution at Wassaic, Dutchess County, which shall be similar to that of Letchworth Village and the enlargement of the present institutions so that a total of 10,000 patients may be kept in-

stead of the 5,000 as at present. The money for these extensions will come from the fifty million dollar bond issue.

UNIFICATION OF ADMINISTRATION

The new law for the administration of the State hospitals and schools groups both in a single department called the Department of Mental Hygiene under a Commissioner. The Department will have three divisions, those of hospitals, schools, and clinics, each under an associate commissioner.

The method of committing patients to the institutions will also be unified, and every doctor who is qualified as an examiner for the insane can also make examinations for mental deficiency, and certify to their need of commitment to a school. Physicians will no longer be in doubt regarding who has jurisdiction over a case, for the same commissioner will handle all cases growing out of mental abnormalities.

CLINICS

The program for the care of the mentally sick would be entirely inadequate if it embraced only the fully developed cases. The great hope of stemming the rising tide of insanity and mental defects consists in prevention while the abnormalities are in a preventable or curable stage. The State has maintained a system of clinics for several years, but has not provided the personnel for carrying on the clinics in a proper manner. The burden of conducting the clinics has fallen on the hospital staffs who already are overworked with the care of the patients who are in the hospitals. Yet the system has been demonstrated to be a great success. Over one fifth of the cases in the Utica State Hospital enter the institution as voluntary cases as the result of advice given to them at clinics. This might seem to indicate that the clinics are filling the hospitals with cases which might not need to go there. But on the other hand, the cases go out practically cured after a short time. After the system is well under way with State-wide control, the great number of advanced cases will probably be much reduced, and there will be an end to the race of constructing new hospitals fast enough to take care of the increasing number of cases.

The State Commission for Mental Defectives also conducts clinics. During the year ending June 30, 1924, clinics were held in 23 centers at which 1,051 cases were examined.

DELINQUENT MENTAL DEFECTIVES

The State supports six institutions for the isolation and care of mental defectives who have criminal tendencies. These are listed in Table 3. A physician who is consulted about a boy or girl, or even an adult in this class, can assist in securing the proper care for the case by obtaining a full history of the case and by using his influence with the parents or relatives to permit the case to be sent to the proper corrective institution. While the institutions are places of detention, yet they are also schools, and in fact some of them are called schools and all should be so named.

den rests on the medical profession to reduce the great cost of the care of the mentally abnormal, and in addition to convert them from a liability to a productive asset. Physicians can do this by taking a more active interest in the art of treating mental diseases. Only one insane person out of thirty is being treated in private institutions, but this may be misleading because many "nervous breakdown" cases who go to private sanatoriums receive treatment which prevents insanity.

Doctors have complacently permitted and even welcomed the entrance of the State into the medical field of psychiatry. A considerable degree of

TABLE III
Institutions for Delinquents

NAME	LOCATION	Year of Opening	Normal Capacity	Number of Cases Present
State Agricultural and Industrial School	Industry, Monroe County	1849	720	689
New York Training School for Girls	Hudson, Columbia County	1893	369	388
New York State Reformatory for Women	Bedford, Westchester County	1901	400	
Western House of Refuge for Women	Albion, Orleans County		200	203
New York House of Refuge	Randalls Island, New York City	1825	1,000	437
Institution for Defective Delinquents	Napanoch, Ulster County		716	487

EPILEPTICS

Craig Colony at Sonyea, Livingston County, was opened in 1896 and is designed for epileptics only. It has a capacity of 1,500 and a present population of 1,580.

ADDRESSES

Physicians wishing information can obtain it by addressing the organizations shown in Table 4.

State medicine is necessary for the control of the insane and mentally deficient, because conditions, socially, economically, and legally require it. But a great deal can be done by the early recognition of cases by family doctors and their treatment while they are in the stage of "Nervousness" which the patients themselves can control with the aid of the family doctor. Every person who is becoming insane goes through a preliminary stage when he is nervous, or sleepless, or excited, or

TABLE IV
Organizations Assisting Physicians in Cases of Insanity and Mental Deficiency

KIND OF CASE	NAME OF ORGANIZATION	ADDRESS
Insanity	State Hospital Commission	Albany, N. Y.
Mental Deficiency	State Commission for Mental Defectives	175 Fifth Avenue, N. Y. C.
Social, Economic and Legal Points	State Board of Charities	Albany, N. Y.
Social Service and General Advice for Defective Children	State Charities Aid Association	East 22nd St., N. Y. C.
Educational	National Committee for Mental Hygiene	370 Seventh Avenue, N. Y. C.

WHAT MAY BE EXPECTED FROM THE BOND ISSUE

The present overcrowding of State institutions is something over 10,000 patients. The bond issue of fifty million dollars will just about take care of this overcrowding. The plan is to expend it over a period of four years.

The annual increment of excess of patients over the capacity of institutions is about 900, and so in four years there will still be a deficiency of 4,000 beds in the State hospitals and schools. But the increased efficiency of care should have marked effect on reducing the number of cases requiring hospital care.

DUTY OF PHYSICIANS TO PRACTICE PSYCHIATRY

The cost of the care of the insane and mental defectives is the third in the list of expenses of New York State, and is exceeded only by the appropriations for highways and schools. A bur-

melancholy, and is conscious of his condition and seeks relief from his family doctor. But the physician too often dismisses the patient and tells him he is merely "nervous." Of course he is nervous—that is what he came to see the doctor about, and the relief of the condition is the practice of preventive psychiatry.

The campaign for the periodic examination might well include the practice of preventive psychiatry as one of its objects.

There is a burden upon psychiatrists to simplify their teaching of the art of practice on mental cases. The field of mental diseases is almost as broad as that of physical ailments, but still there are a few fundamental points in mental pathology just as there are in physical pathology. A psychiatrist will yet arise who will simplify and clarify, and glorify the art of the practice of psychiatry within the comprehension and desire of the family doctor.

SOCIAL SERVICE IN MENTAL HYGIENE

By HOMER FOLKS, Secretary
State Charities Aid Association, New York

The State Charities Aid Association, which organized the County Committees on Tuberculosis and Public Health, is no stranger in the field of mental hygiene. In fact, since its organization in 1872, one of its constant objectives has been better care and wiser dealings with the insane and feeble-minded. Whatever may be the obscure origins of various types of mental disease and deficiency, their development brings immediately in its train most important social consequences, to the patient, and to his family and community. Nothing more completely wrecks family life from an economic, educational, and humane point of view than mental disturbance. In its early stages, it leads to baffling misunderstandings, to increasing discord, to diminishing income, and hastens rapidly toward catastrophe. When the condition is recognized for what it really is, the family situation must be wholly readjusted. Likewise, when the patient recovers, he returns to a family circle which is very different from that which he left. Standards of living have radically changed, responsibilities for income production have been shifted to other shoulders. To re-establish himself in a new and altered household would test the mettle, in many cases, of an entirely well and exceptionally balanced person, for the convalescent patient, fresh from the routine of hospital life, released from daily medical supervision, assuming again burdens from which he has been wholly free for months or perhaps years, the problem of readjustment is Herculean.

It is rather surprising that the recognition of the necessity of social service in, so to speak, binding up the wounds of the mentally disturbed patient, in re-establishing ties that have been severed, in regaining a status in family, community, and economic life, has come so late. It is, in fact, just twenty years ago that "after-care for the insane" was established in this State, as something of a pioneer experiment in America. It began, as many other social innovations have begun, in a voluntary way, but at the request of, and with the full cooperation of the public authorities. The State Hospital Commission requested the State Charities Aid Association to organize local Committees of citizens to assist patients released on parole, or discharged as recovered, to re-establish themselves in their communities. Several of these Committees were appointed, some working wholly as groups of volunteers, others, in the larger centers, employing trained social workers. The demonstration period was brief. In a very few years the success of the undertaking, from a humanitarian and from a financial point of view, was evidenced. Patients could be released from State Hospitals

considerably earlier, the cost of new construction could be considerably reduced, the census of the hospitals with its high per capita cost could be diminished, so the State, itself, was authorized to employ "field agents," as they were at first termed, in connection with each State Hospital, working with physicians from the hospitals in holding clinics in various centers in the hospital districts, primarily for patients on parole, but also to advise and assist patients whose disease had not as yet required commitment, in the hope that in some cases commitment might be prevented altogether, and that in others, dependable diagnosis and helpful treatment might begin at a much earlier date. A little later on the State adopted a ratio of one field worker to every one hundred patients on parole, and automatically increased the number of field workers from year to year in ratio with the growth of the parole system. At the present time, there are some forty field workers connected with the thirteen hospitals. Their work is wholly extra-mural, and they represent a constructive social force of the highest value.

In regard to the feeble-minded, there is, as yet, only the merest outline of a State system of home supervision, but here, again, voluntary agencies are supplementing and leading the way for what we may hope will become a much more highly developed State system.

This brief article set out to describe the work of the State Charities Aid Association County Agents for Dependent Children. In considerably more than half of the counties of the State, the State Charities Aid Association has appointed a local Citizens Children's Committee, which has entered into contractual relations with the Board of Supervisors. The Children's Committee employs a trained social worker, known as the County Children's Agent, provides an office, a telephone, and means of transportation, the Board of Supervisors makes a grant toward these purposes, and the Citizens Committee raises the remainder. The agent is given such official status as need be, but does not depend particularly upon official relationship. She is often made an assistant to the County Superintendent of the Poor, a Probation Officer of the Children's Court, an Investigator of the Board of Child Welfare (Widow's Pensions), but, in fact, she is, as a rule, the only trained worker in the county dealing with needy children, and when any child is in trouble, everyone naturally turns toward her for information and advice. Her job is simply to see that every child who gets into trouble or need receives as nearly as may be, the particular kind of help which that child in that particular

family needs, and to see that the child gets it quickly

Naturally, a good many of the children who get into trouble are more or less mentally deficient, so that any County Children's Agent becomes, in considerable degree, in fact, a County Agent for the Feeble-minded. She must depend very largely upon professional advice. She must secure medical examinations of these needy children, and also psychological tests and mental examinations. When these medical examinations have been made, the mental tests given, and, when need be, an examination by a psychiatrist secured at a State Mental Clinic, it is up to the agent to see that whatever needs to be done, is actually done. This is where the hard part begins. Many are they who are willing to give good advice and very necessary information, but those who are available for help in the subsequent social service are relatively few. She must be a resourceful person, widely informed, gentle and sympathetic in approach, discreet, able to receive and hold confidence, not visionary, adaptable to all situations, not above the many menial tasks and disagreeable things which constitute so large a part of social service for the mentally deficient.

In this inclusive assortment of social tasks,

these County Children's Agents receive daily invaluable assistance from the medical profession, practically without exception, their services in diagnoses and advice are given freely and constantly. The notable success which has attended the work of these County Children's Agents would have been impossible without such co-operation. The necessity for understanding and mutual helpfulness has been so obvious that it has not awaited any action on the part of the State headquarters of the local groups concerned.

To the physicians, it has been a great relief to have available the services of a trained social worker, who could take up the tangled threads of a mentally deficient personality and bring such order and stability and development into the situation as the patient's endowment permitted.

We are only on the threshold of the development of early diagnosis of mental deficiency, and of sympathetic and effective service, medical and social, to the end that each of the mentally deficient may be saved from serious catastrophe, and may realize for himself and his community the most that his talents permit. In the working out of such a broader and more effective program, the local physician and the County Children's Agents, with their intensive experience, will undoubtedly lead the way.

THE NATIONAL COMMITTEE FOR MENTAL HYGIENE

By GEORGE S STEVENSON, M D

Certain organizations have been developed to care for the problem of mental hygiene in its various phases. These organizations are clearing houses for knowledge on the subject and the conditions existing in their territory. The New York State Hospital system is organized to care for those who have already recognizable mental deviations. A similar system treats similarly of the feeble-minded. These deal with end results. New York, as is the case with some other states, looks as well to prevention, and so, as a branch of the State Charities Aid, there has been developed a mental hygiene division to look after this phase. The National Committee for Mental Hygiene is an organization of similar interests, national in scope. It is prepared to offer to physicians several services whereby in part it hopes to help prevent mental disease. Its quarterly journal of Mental

Hygiene presents the latest reports on mental hygiene problems and a critical review of the literature. Pamphlets and reprints are available at a nominal cost. The library is equipped to furnish bibliographies on special topics and reading lists are available. A list of the psychiatric facilities of any district can be furnished, assistance is given in organizing mental hygiene societies or study classes. Personal consultation is possible and advice given in the planning of post-graduate courses. The Committee offers several fellowships in psychiatry. The National Committee needs the support, cooperation and active interest of the general practitioner as a leader in his district. It tries to give in return something that will meet his needs.

The headquarters for the National Committee for Mental Hygiene is at 370 Seventh Avenue, New York City.

NEWS NOTES

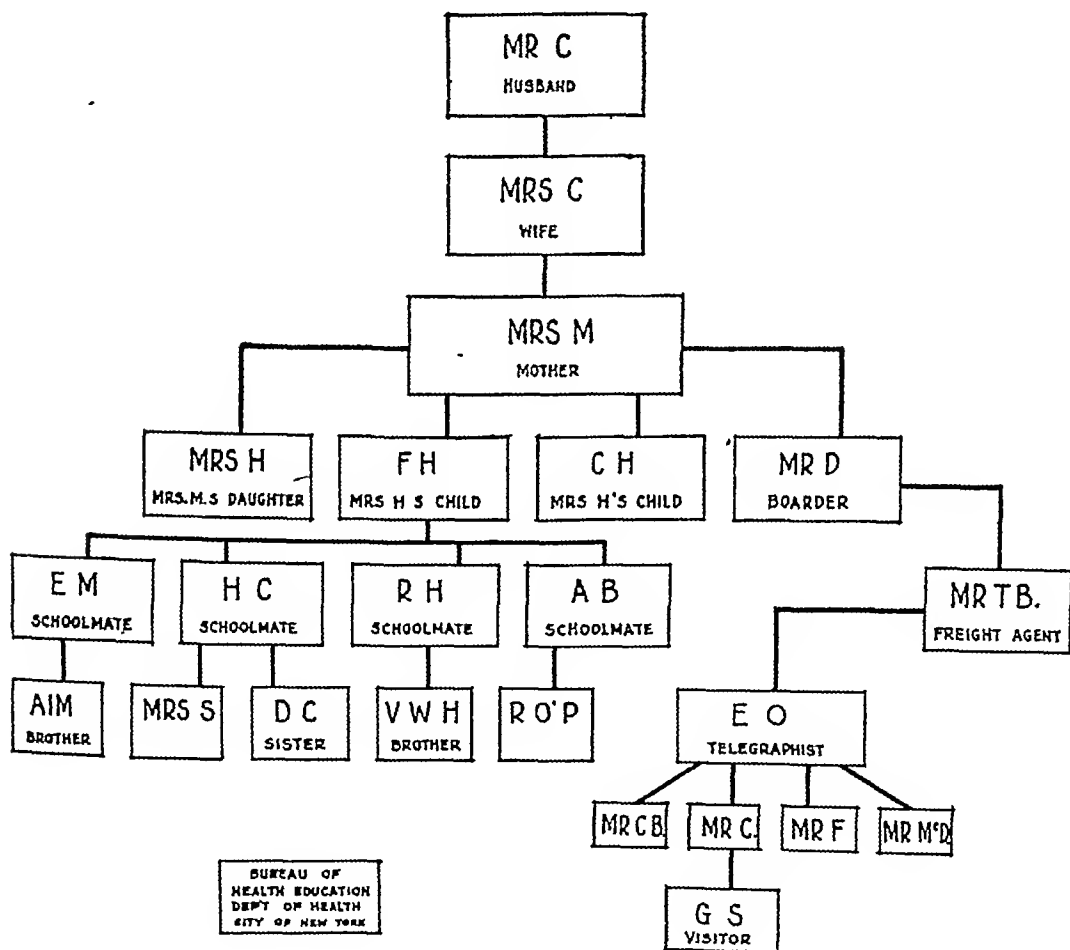

IT SPREADS LIKE WILDFIRE

From the Weekly Bulletin, New York City Department of Health, April 17, 1926

The test of the pudding is in the eating—and that of smallpox in the spreading—among the unvaccinated. Below is a graphic chart presenting the ramifications of infection among a group of unvaccinated, the original source of infection being traceable to Mrs C, the wife

quarantine and vaccination. This incident, however, not only illustrates the wildfire character of smallpox, but also the menace to public health of the unvaccinated.

Not one of the cases listed had ever been successfully vaccinated. Had not smallpox been

of a traveling salesman, who, coming from Canada, brought with her a ripe case of smallpox. From this single source of infection 22 persons contracted the disease. How many more might have developed smallpox is impossible to say, for thanks to the vigilance of the doctors and health authorities, the spread was checked by

introduced into their midst they would have lived on without ever suffering the disease, but once the infection was introduced into their midst it spread like veritable wildfire. The warranted deduction is all too evident. *Vaccination for individual and public safety!*

NEWS NOTES

THE SENECA COUNTY MEDICAL SOCIETY

The semi-annual meeting of the Seneca County Medical Society was held at the Citizen's Club, Seneca Falls, on Thursday, May 13th

The morning business session was followed by a luncheon at the Gould Hotel after which the Society reconvened for a scientific session

Dr J M Swan, in charge of the publicity work in New York State of the American Society for the control of cancer, spoke on the role of the private physician in the early diagnosis and prevention of cancer. A very interesting discussion, led by Dr Elliott, followed Dr Swan's remarks.

The Society was then addressed by Dr John R Williams of Rochester, who spoke on High Blood

Pressure. Dr Williams gave the modern conception of high blood pressure, spoke interestingly of the experiments he carried out while in Toronto and of the treatment of patients with this condition, emphasizing especially keeping these patients within normal weight limits and giving them plenty of rest. He spoke of associated conditions of nephritis and arterio sclerosis and emphasized the importance of the specific gravity of day and night urine as indicative of serious renal impairment if it does not vary.

Dr Lester W Bellows, Waterloo, N Y, read a very interesting biography of Dr Coventry, the second practicing physician of Seneca County.

NASSAU COUNTY NEWS

The physicians of Glen Cove, Nassau County, wish to publish their appreciation of their late colleague, Dr E Raymond Schilling, who died at the age of thirty-six on April 24, 1926, from pneumonia following an apparent convalescence from septicemia acquired in his line of duty.

Dr Schilling was patriotic and public spirited,

and had the respect and confidence of the medical profession and the community. He served three years in the State Guard and over two years in the Navy during the World War. He was active on the staffs of the Glen Cove and the Nassau Hospitals.

BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on April 21, 1926, was called to order at 9 P M, the President, Dr Cuniffe, in the Chair.

The Scientific Program proceeded as follows:

Dr A Lobell presented a Lantern Slide demonstration of A New Method of Irrigating the Sphenoidal Sinus.

Dr William H Park read a paper on "Our Present-Day Ideas of Scarlet Fever." Dr Abraham Zingher and Dr I H Goldberger discussed this paper and the discussion was closed by Dr Clark.

Dr Louis I Harris, Commissioner of Health of the City of New York, addressed the Society on the general subject of Public Health, dealing with the problems of Preventive Medicine, Public Health Education, Periodic Health Examinations and Milk Inspection. Dr Harris further emphasized the need of the Bronx Health Department being housed in suitable quarters, which should be the Health Centre of the Bronx, and suggested that it might be the headquarters of the Medical Profession of the County as well. He strongly urged the active participation of the Society in this problem.

Election of candidates being in order, it was moved and carried that the Secretary be instructed to cast one ballot for the following candidates for membership: Morris I Knoppfelmacher, Maurice S Rosen, Felix R Sabatini, Aaron Scheffan, Nathaniel Uhr.

Dr Friedman presented the Report of the Committee on Public Health and Medical Education with particular reference to the subjects of Public Health and Periodic Health Examinations.

It was moved and carried that the Society go on record as favoring an appropriation for the building of suitable quarters for the Health Department of the Bronx, as suggested by Commissioner Harris, and that this matter be referred to the Comitia Minora to study ways and means of furthering this project.

The Committee on Legislation reported that the so-called Chiropractic Bill was defeated both in the Senate and the Assembly. The Medical Practice Act has been passed by the Senate and Assembly and will go to the Governor for his signature.

It was moved and carried that the Bronx County Medical Society extend a vote of thanks to Dr William H Park and Dr Louis I Harris.

THE DAILY PRESS

CLIMATE AND HEALTH

The weather is popularly believed to have a great effect on health, but a "change of climate" is now prescribed far less frequently than formerly. Some excellent authorities even advocate a climate that is changeable, because the changes are stimulating rather than depressing. The New York *Herald-Tribune* of February 24 quotes an interview with Dr. Charles H. Mayo, as follows:

"People who run South when the frost makes pictures on the window panes are jeopardizing their health", according to Dr. Charles H. Mayo, surgeon, of Rochester, Minn. The famous man had just returned yesterday from a West Indies cruise on the North German Lloyd liner *Columbus*, but he does not consider a trip like that comparable to loafing in Florida.

"People living in the temperate climes need the weather changes to keep their bodies functioning properly, he feels, for they need certain things indigenous to the sections in which they live.

Only to those who are in bad health should the advertisements for wintering in the South apply, he holds.

"He held up the mail man as a shining example of what exercise, good eating and fidelity to the home town can do for a man. The American mail man, he believes, is the healthiest of all the people in the country. He has to walk a lot, carry burdens which exercise muscles that walking does not touch, eat more or less frugally because of his wages and travel but little. These things make him what he is, Dr. Mayo said.

"The human body to Dr. Mayo, who has seen it in all of its worn out state, is not an imperfect piece of mechanism. He has seen many men he regards as physically perfect, and always they are men who exercise well and eat carefully.

"We are still digging our graves with our teeth," he said, when emphasizing the importance of diet."

DIETARY HABITS

Food and infection are by far the leading causes of sickness and disability. Those operating less frequently are fatigue, accidents, and malignant new growths.

Food and infection often operate together, but food alone may also produce sickness and disability.

Food habits are among the most persistent characteristics of both individuals and races. Unreasoning likes and dislikes are dominant factors in choice of food to such a degree that they are likely to over-ride all considerations of health.

Fashions in foods and eating places come and go like those in dress and the theatre, but there is constant progress in the healthfulness of prevailing diets. Six points of comparison may be made between present-day diets and those of a generation ago.

1 Quantity. It is now fashionable to have small portions exquisitely served, rather than overflowing dishes which invite overindulgence.

2 Variety. All kinds of food may now be obtained throughout the year. The vitamins of fresh fruits and vegetables are as available in winter as in summer, and the incipient form of scurvy, called "spring fever" is now seldom seen.

3 Composition. Present day diets contain an excess of carbohydrates, as compared with pro-

tein of rich meat dishes of a generation ago. Sugar rather than meat is now the object of warning in dietary advice. Ice cream and candy are the foods which people today use to excess.

4 Quality. Food of all kinds are now fresh, crisp, and tasty, in contrast with the wilted undesirable vegetables and fruits of a few years ago. Cold storage has enabled producers to conserve great reservoirs of perishable foods during seasons of plenty for use through periods of new production.

5 Purity. Foods are now what they are claimed to be, and adulterations are uncommon. In fact, food is too pure—for example, white bread and polished rice.

6 Infection. Food is handled in a clean manner, and an increasing proportion of the handlers are examined for the detection of carriers.

The effects of modern dietary habits are plainly seen in the people who walk our streets. The babies in the go-carts are well-nourished and alert, and boys and girls are sturdy and active, and young matrons are fair and plump. Poor nourishment is seldom seen, but rather slimness is usually desired on the ground that it is unusual and is a distinction. Only among elderly people are the marks of dietary indiscretions seen, for those who have been brought up under the newer fashions of eating have not yet had time to reach old age.

The response to both errors and correctness in diet is rapid and pronounced during the two extremes of life. Babies and youths react quickly to their foods, and the aches and nervousness and insomnias of elderly people yield to diet better than to any other therapeutic measure.

Young adults are relatively immune to the effects of errors of diet. They can gorge themselves with sweets and ice cream for twenty years, but then comes the day of reckoning when nature demands the penalty for disobedience to her laws of nutrition and excretion. Rare indeed is the person over fifty who is not annoyed with "rheumatism" or other form of punishment for dietary sins committed through early adult years.

Eating houses reflect modern enlightenment regarding diet. One chain of ubiquitous restaurants prints on its menus the number of calories contained in the portions that are served—a most valuable public health measure. Moreover, the changing fashions in eating, like those of dress, tend to more healthful living.

These reflections are inspired by an editorial entitled "Modes of Eating," in the May 17th issue of the *New York Sun*, which reads as follows:

"Fashions in eating change so rapidly in New York that getting food sometimes seems unimportant compared to the manner in which it is obtained. Only a short time ago the arrival of the delicatessen restaurant was celebrated. In this aromatic retreat it was possible to select the kind of cold meat or sausage, salad or cheese that seemed most appetizing and eat it then and there on the tables provided in more or less elaborate dining rooms instead of buying and taking the viands home or surreptitiously munching them on the street or in the shop.

"The delicatessen restaurant removed this informality and made it possible to enjoy the slice of cold ham or beef, potato salad or coleslaw,

American cream cheese or Camembert, in something like appropriate surroundings. The definite arrival of the new type of eating house was duly noted and appreciated.

"It followed, to be sure, a variety of other eating places. There was the dairy lunch, which gradually extended its offerings until milk and cereals became a negligible part of what it had for the hungry New Yorker. Then there was the rotisserie, with its fowls and meats browning on the spit. The automat taught the delight of watching one's money do its work by opening the compartment in which the dish revealed itself as in a show window waiting to be enjoyed.

Service has become the slogan of more than one man and society today. It took the well-established reign of the cafeteria to teach the delights of self-service at meals. The tearoom took its place in the list and improved so much on its original purpose as to sell course meals at fixed prices.

"Now it is the sandwich shop which strikes the latest hour in the facilities that our citizens have for their sustenance. It is likely to be described as "Ye," although that form of the definite article had gone out of use long before the reign of George III, in which the Earl of Sandwich, who gave this casual food its name, held sway. Thrifty of time if not of pelf, he ate as he played. It might be thought that the population has suddenly decided that no other form of food is wholesome. Whatever the reason, the sandwich shop has become the latest form of taking nourishment on the wing."

Regarding the derivation of the word "sandwich," the *Century Dictionary* says: "Named after John Montagu, Fourth Earl of Sandwich (died 1792) who once spent twenty-four hours at the gaming table without other refreshment than some slices of cold beef placed between slices of toast."

SMALLPOX

The *New York Sun*, May 24, contains the following excellent editorial on smallpox in the United States:

"With all the States except Utah accounted for the American Association for Medical Progress reports that health authorities in the United States recorded 43,193 cases of smallpox in 1925. Only one country in the world has a worse record, that is India. India has more inhabitants than this country, but this country has a much higher plane of living than India. The facts are not in any degree creditable to the United States."

"There is nothing sectional about the distribution of smallpox, there is nothing mysterious about its incidence. It occurs where the completely established efficacy of vaccination to prevent it is ignored, where proper sanitary measures are not adopted. If Rhode Island had enforced vaccination as the other New England States did it would not have had nearly a hundred cases in 1925, if other States lived up to the same standard they would not have such disappointing records as they have."

BOOK REVIEWS

DISEASES OF THE HEART By SIR JAMES MACKENZIE, F.R.S., M.D., F.R.C.P. Fourth Edition Royal octavo of 496 pages with 342 illustrations London, Humphrey Milford New York, Oxford University Press, 1925 Cloth, \$9.00 (Oxford Medical Publications.)

The fourth edition of Mackenzie's work on the heart is an entirely new book. It was completed shortly before his death, and is published posthumously. The author has always been known as an original observer and thinker and a vigorous writer. For some years before his death he was engaged in an endeavor to simplify and clarify methods of investigation. He states that there is such an array of unrelated physiological and clinical data being industriously turned up by research workers that no one could possibly assimilate them and that they are simply adding to the confusion, that what is needed is a more profound study of elementary process, so that all clinical phenomena can be reduced to the terms of a few fundamental laws. So equipped, the physician would be able to accurately ascertain the diagnosis, gauge the prognosis and plan the treatment in any given case. Mackenzie particularly stresses prognosis.

Every thoughtful medical worker will have much sympathy for this ideal, and no doubt this vigorous statement of the problem and the author's enthusiastic attack upon it will stimulate fruitful work upon basic functions that we should know more about. We are inclined to suspect, however, that Mackenzie, sensing that he was saying his last say, threw into his argument more emphasis than he would have employed had he expected an opportunity for rebuttal. Always impatient of opposition, in this last word he has so vigorously attacked the whole medical profession, their minds and their methods, that the medical reader must promptly throw up his hands in surrender—or put them up in defense.

So—the reviewer finds himself compelled to dissent from the opinion that medical research as now conducted is a waste of time, while admitting the advantage of further study of elemental processes. Turning to the author's own contribution along these lines, we find that his argument is largely based upon a so-called "physiological axiom," which is qualified with a "probably" the first time it appears, the qualification being soon forgotten as the superstructure of argument is developed. This refers to the statement that of the two phases of cell life, periods of discharging energy and of renewing energy, that the latter is variable, while the former is "probably" constant. (p. 52.) The assumption of the universality of this rule does not seem warranted.

A master key for the explanation of all symptoms is offered in "the principle of the reflex arc," which means that in considering the pathological activity of any structure, its controlling or modifying attachments should be scrutinized. A very illuminating reminder, but his corollary that the structure itself should be disregarded is certainly illogical (vide the discussion on the nature of auricular fibrillation, p. 185).

The genetic system, which is discussed at length, is held responsible for most of the ills the heart is heir to. Of its functions, one of the most important is a mysterious property called "control." Explanations using this word do not explain.

From such bases the author comes to many conclusions which differ radically from accepted current opinion, which are certainly unproven, and which appear unlikely to be true.

On the other hand, the book abounds with flashes of

wisdom, gleaned through many years of careful clinical study—a method which the author deprecates as wasteful of time and unnecessary. We appreciate them none the less, particularly from the center of some thicket led into by one of his short cuts. T. H.

SWANZY'S HANDBOOK OF THE DISEASES OF THE EYE AND THEIR TREATMENT Thirteenth Edition. Edited by LOUIS WERNER, M.B., F.R.C.S.I., Sen. Mod. University of Dublin. Surgeon to the Royal Victoria Eye and Ear Hospital. Illustrated. P. Blakiston's Son & Co., Philadelphia, 1925 Price, \$6.50

This very excellent book has reached its thirteenth edition, which is a good measure of its worth. It is the opinion of the reviewer, that it is the best reference book on the eye of a handy size. Sir Henry Swanzy, the original author, died after the publication of the tenth edition. Since then Werner has continued to edit the succeeding editions. He has very evidently endeavored to keep it up to date and abreast of the latest knowledge of ophthalmology.

There has been no great change in the text in this latest edition from the preceding one. The principal change noted is the grouping of the Diseases of the Iris and Ciliary Body in one chapter, and those of the Choroid and Retina in another. This is a more logical arrangement to our mind than that in the preceding edition.

It is excellently printed and well bound.

CHAS. A. HARGITT

THORACIC SURGERY The Surgical Treatment of Thoracic Disease. By HOWARD LILIENTHAL, M.D. Two octavo volumes totaling 1,294 pages, with 90 illustrations, 10 in colors. Philadelphia and London W. B. Saunders Company, 1925 Cloth, \$20.

As we view these volumes both the author and the publisher should have the satisfaction that results from hard work well done.

The scholarly mind of the author and his wide experience and special training in thoracic surgery have left their indelible impression. Dr. Lilienthal has been fortunate in securing the co-operation of many of the best known authorities of the country in the preparation of special chapters.

Evarts Graham writes on Physiology, Jaches on Roentgenology, Branower on General Anaesthesia; Ottenberg on Blood Transfusion, Lusk discusses the Intravascular Treatment of Thoracic Aneurysm with gold wire and galvanism, and Amberton and Peters of the Loomis Sanitarium give a lengthy article on the Treatment of Pulmonary Tuberculosis by Induced Pneumothorax.

Other chapters deal with all the separate organs contained in the thorax without the omission of such structures as the thoracic duct and the phrenic and cervical sympathetic nerves in their relation to thoracic disease. The final chapter deals with Military Surgery.

The type is clear the paper of splendid quality, and the numerous illustrations, photographs, reproductions of X-ray plates and colored plates add greatly to the value of the work. The bibliography of six and a half pages bears mute testimony to the fact that Dr. Lilienthal has consulted and quoted freely from other authors.

In the future those who wish to devote special time to the study of this important and difficult branch of surgery will early find it necessary to secure these volumes.

HENRY F. GRAHAM

The response to both errors and correctness in diet is rapid and pronounced during the two extremes of life. Babies and youths react quickly to their foods, and the aches and nervousness and insomnias of elderly people yield to diet better than to any other therapeutic measure.

Young adults are relatively immune to the effects of errors of diet. They can gorge themselves with sweets and ice cream for twenty years, but then comes the day of reckoning when nature demands the penalty for disobedience to her laws of nutrition and excretion. Rare indeed is the person over fifty who is not annoyed with "rheumatism" or other form of punishment for dietary sins committed through early adult years.

Eating houses reflect modern enlightenment regarding diet. One chain of ubiquitous restaurants prints on its menus the number of calories contained in the portions that are served—a most valuable public health measure. Moreover, the changing fashions in eating, like those of dress, tend to more healthful living.

These reflections are inspired by an editorial entitled "Modes of Eating," in the May 17th issue of the *New York Sun*, which reads as follows:

"Fashions in eating change so rapidly in New York that getting food sometimes seems unimportant compared to the manner in which it is obtained. Only a short time ago the arrival of the delicatessen restaurant was celebrated. In this aromatic retreat it was possible to select the kind of cold meat or sausage, salad or cheese that seemed most appetizing and eat it then and there on the tables provided in more or less elaborate dining rooms instead of buying and taking the viands home or surreptitiously munching them on the street or in the shop.

"The delicatessen restaurant removed this informality and made it possible to enjoy the slice of cold ham or beef, potato salad or coleslaw,

American cream cheese or Camembert, in something like appropriate surroundings. The definite arrival of the new type of eating house was duly noted and appreciated.

"It followed, to be sure, a variety of other eating places. There was the dairy lunch, which gradually extended its offerings until milk and cereals became a negligible part of what it had for the hungry New Yorker. Then there was the rotisserie, with its fowls and meats browning on the spit. The automat taught the delight of watching one's money do its work by opening the compartment in which the dish revealed itself as in a show window waiting to be enjoyed.

Service has become the slogan of more than one man and society today. It took the well-established reign of the cafeteria to teach the delights of self-service at meals. The tearoom took its place in the list and improved so much on its original purpose as to sell course meals at fixed prices.

"Now it is the sandwich shop which strikes the latest hour in the facilities that our citizens have for their sustenance. It is likely to be described as "Ye," although that form of the definite article had gone out of use long before the reign of George III, in which the Earl of Sandwich, who gave this casual food its name, held sway. Thrifty of time if not of pelf, he ate as he played. It might be thought that the population has suddenly decided that no other form of food is wholesome. Whatever the reason, the sandwich shop has become the latest form of taking nourishment on the wing."

Regarding the derivation of the word "sandwich," the *Century Dictionary* says: "Named after John Montagu, Fourth Earl of Sandwich (died 1792) who once spent twenty-four hours at the gaming table without other refreshment than some slices of cold beef placed between

SMALLPOX

The *New York Sun*, May 24, contains the following excellent editorial on smallpox in the United States:

"With all the States except Utah accounted for the American Association for Medical Progress reports that health authorities in the United States recorded 43,193 cases of smallpox in 1925. Only one country in the world has a worse record, that is India. India has more inhabitants than this country, but this country has a much higher plane of living than India. The facts are not in any degree creditable to the United States."

"There is nothing sectional about the distribution of smallpox, there is nothing mysterious about its incidence. It occurs where the completely established efficacy of vaccination to prevent it is ignored, where proper sanitary measures are not adopted. If Rhode Island had enforced vaccination as the other New England States did it would not have had nearly a hundred cases in 1925, if other States lived up to the same standard they would not have such disappointing records as they have."

MEDICAL HEREDITY Distinguished Children of Physicians (United States, to 1910) By WILLIAM BROWNING, Ph.B., M.D. Octavo of 250 pages Baltimore, The Norman, Remington Company, 1925 Cloth, \$4.00

This volume is a masterpiece. It is the culmination of the life-hobby of one of our own profession whose versatility and scholarly attainments are internationally recognized. The treatment of the subject is entirely unique, and the mass of statistics, covering over 3,000 physicians in the United States and mentioning some 6,500 persons altogether, is so large as to certify correct evaluations. A new field has been entered upon which must prove fascinating and of fundamental importance, not alone "in the general sense" of heredity, as the author puts it, but from the biological angle of amphimixis—gametes, zygotes and genes.

It is evident from the first page throughout the whole work that Dr Browning has made an intensive study of his subject, applying original concepts to the general arrangement and so classifying his data as to stimulate thought and make deductions simple. His own theory of what he has accomplished combines modesty with the charm of suggestiveness without dogmatism. Only a mind trained to logical thought, coupled with an indomitable "will to do" could project and carry on, through a long period of years, so important an undertaking, and the fact of its successful completion justifies the prediction that it will receive wide and favorable recognition and find a chosen place on the shelves of many physicians, biologists and intellectuals generally.

It has seemed a somewhat ambitious task to review critically a work of such depth, but a life-long acquaintance with the author and the exhilaration of having read a book so "out of the usual" makes the attempt perhaps legitimate.

J M VAN COTT

TAYLOR'S PRACTICE OF MEDICINE. By E. P. POULTON, A.M., M.D., Oxon., F.R.C.P., Lond., Physician Guy's Hospital with assistance of C. PUTNAM SEYMOUR, M.A., M.D., Oxon., F.R.C.P., Lond., Assistant Physician for Nervous Diseases, Guy's Hospital, H. W. BARBER, M.A., M.B., Camb., F.R.C.P., Lond., Physician in charge Skin Dept., Guy's Hospital. Thirteenth Edition, 48 plates (8 colored) 93 text-figures. P. Blakiston's Son & Co., Philadelphia, 1926 Price, \$9.00

This volume contains some thousand pages of closely printed matter. In this revision many alterations have been made in the text and much new matter added to bring this standard work up to date. The contents are well arranged, and most of the well proven knowledge on the subjects considered is included. It follows the same general plan as most text-books of this type, and will prove of value as a short reference work.

J ARTHUR BUCHANAN

PRACTICAL OBSTETRICS By E. HASTINGS TWEEDY, M.D., F.R.C.P.I. and G. T. WRECH, M.D., in collaboration with BETHEL SOLOMONS, M.D., F.R.C.P.I. Fifth Edition. Octavo of 617 pages with 159 illustrations. London, Humphrey Milford, New York, Oxford University Press 1925 Cloth, \$6.25 (Oxford Medical Publications)

This work needs no introduction in the obstetrical field. It is recognized as a standard text. In this latest revision the senior author has had the assistance of Dr Solomons in bringing this already excellent book up to date. It probably summarizes the best thought in English obstetrics of today coming as it does from the wealth of material of the Dublin Rotunda Hospital. The tables in the appendix are particularly of value. We have only one suggestion to make for future editions and that is in the uniformity of measurements, using either centimeters or inches.

W P

CANCER, POST-GRADUATE LECTURES Delivered under the auspices of the Fellowship of Medicine Edited by HERBERT J. PATERSON. Preface by Sir JOHN BLAND-SUTTON, LI D., F.R.C.S. Illustrated William Wood and Co., New York, 1925 Price, \$4.00

This volume of 186 pages containing eleven lectures on various aspects of cancer delivered as the title page states and published "in the hope that they may appeal to a wider audience."

We share the hope. Not only because a somewhat similar enterprise of our own has somewhat sensitized us to the idea but because we think they deserve to be several reasons.

First—because they are practical. Each one of the lectures deals with some one phase of the great subject which is the title of the book, discusses it simply and directly, offering without hesitation, individual opinion and ending always on the keynote of Treatment.

It is a refreshing book. We have seen several books on cancer lately of which this could not be said. There seems to be a subtle temptation in dealing with that subject to wander into fields of mysticism or charlatanry or both.

We recommend to all those who have discovered or are about to discover a cure for cancer a prayerful perusal of this simple and straightforward little book.

J E J

APPLIED BIOCHEMISTRY By WITHROW MORSE. Octavo of 958 pages with 257 illustrations. Philadelphia and London W. B. Saunders Company, 1925 Cloth, \$7.00

This volume is made up of 958 pages of close reading matter and 257 illustrations. The author has divided the work into eighteen chapters in which he stresses the important basic biochemical facts and principles which bear directly upon the subject of medicine. Special chapters are devoted to the consideration of the enzymes, the energy producers, food values, energetics of nutrition and the metabolic studies on blood and urine. The chapter on the fate of absorbed materials, intermediate metabolism will be found most interesting and instructive to the physician interested in the diseases of metabolism of carbohydrate and fat and the structure and relations of the internal secretions.

On the whole, the entire subject is presented in an interesting style and the reader is not wearied by excessive technical detail.

H M FERRELLATT

A COMPANION TO MANUALS OF PRACTICAL ANATOMY By E. B. JAMESON, M.D., Senior Demonstrator and Lecturer on Anatomy, University of Edinburgh. Second Edition. William Wood and Co., New York, 1925 Price, \$5.00

This is a second edition of this excellent little volume intended as a companion to manuals of practical anatomy. It contains a very abbreviated, but at the same time, all of the essential points necessary for the thorough understanding of practical anatomy. The author has evidently spent considerable time and thought in the arrangement of this one volume, in order to cover the subject so well.

The volume is small, and is as readable as any manual of anatomy could possibly be.

The subjects treated in the first edition have been brought up to date, and a number of the chapters have been rewritten, as for instance the one on the lymphatic system, which is much more understandable than the chapter on the same subject in the first edition. The chapter on development is a most excellent one, and gives the student of anatomy a very concise and practical understanding of embryology. This is probably the best of the recent one-volume manuals on practical anatomy, and one that should be a most useful book for the student of anatomy, the surgeon, and the teacher of anatomy.

HERBERT T. WIALZ

CLINICAL RESEARCHES IN ACUTE ABDOMINAL DISEASE.
By ZACHARY COPE, B.A., M.D., M.S. (Lond.), F.R.C.S. (Eng.) Octavo of 148 pages with illustrations. London, Humphrey, Milford, New York, Oxford University Press, 1925. Cloth, \$4.00 (Oxford Medical Publications)

This little book is a most valuable addition to the literature on the "acute abdomen." The author has studied the symptoms and common physical findings in a very large number of acute abdominal cases and has then made careful observations of the findings at operation or autopsy. These data have been of value in estimating the real significances of the various symptoms and signs of disease. Too often an opinion has been based only on the personal opinion of some teacher or writer, biased in favor of some sign bearing his name. The author discusses the real value of such signs as muscular rigidity, tenderness, hyperesthesia and referred pain, and presents some very instructive ideas in regard to them.

His chapter on the study of phrenic shoulder-pain is one of the most beautiful clinical studies ever published. "The Differential Diagnosis between Acute Thoracic and Acute Abdominal Lesions" is invaluable and the chapter on perinephric abscess is extremely instructive.

The book is certainly worth adding to any library of works on diagnosis.

A

THE ART AND PRACTICE OF MEDICAL WRITING. By GEORGE H. SIMMONS, M.D., Editor and General Manager Emeritus, American Medical Association, and MORRIS FISHBEIN, M.D., Editor, *The Journal of the American Medical Association*, Chicago. American Medical Association Press, 1925.

This is unquestionably the best book that has ever been published on the subject of the technic of medical writing. It is a compendium of indispensable information boiled down to its essence. The reviewer has found from personal experience that the perplexing questions that constantly arise in the course of the preparation of medical literature are answered in this manual as in no other work of reference. The physician who attempts to write a medical paper without the assistance of "The Art and Practice of Medical Writing" is working under a definite handicap.

A valuable feature is the complete list of bibliographic abbreviations. It is unfortunate, however, that the abbreviations and the form of reference adopted by the American Medical Association differ from that of the "Index Catalogue" of the Surgeon General's Office and the "Index Medicus." The latter publications adopted a satisfactory standard for references years ago. The adoption of a new standard for references by the American Medical Association has not simplified the work for the reader who must refer to all indexes. This is not meant as an adverse criticism of the American Medical Association's style of reference but as a plea for uniformity.

FREDERIC DAMRAU

MAN HIS MAKING AND UNMAKING. By E. BOYD BARRITT, M.A., Ph.D. Thomas Seltzer, New York, 1925. Price, \$2.50.

Humanology is the term coined by the author to cover his subject which he considers too broad in scope to be confined merely to psychology. He deals with slightly abnormal individuals, such as the narcotomaniac and the pyromaniac, in interesting detail, but, in our opinion, the most interesting chapter is that entitled "Explaining Away Religion" which discusses the conflict of religion and psychoanalysis and the undermining of preconceived religious ideas through the development of this new science. The book is instructive and the worthy aim of the author, who is greatly interested in the welfare of mankind, to help man attain self-adjustment in life to normal, healthy existence, is not in vain.

M. L. A.

GENIUS AND DISASTER, STUDIES IN DRUGS AND GENIUS. By JEANNETTE MARKS, Professor of English Literature, Mount Holyoke College. Adelphi Co., New York, 1925. Price, \$3.00 net.

This book is an essay on the relation of genius to drug addiction, disease poisons, and insanity, as exemplified in the lives of certain famous writers. It is more literary and social study than a medical one, as would be expected from a professor of literature, but the author shows a considerable acquaintance with the subject of drug addiction in some of its aspects.

The author refers to the debt which the world owes to the geniuses whose lives were wrecked by the above mentioned agencies, which were used by them in the production of their contributions to the advancement of civilization and culture, she speaks of the "type of writer or artist who is inspired only when he is mad", and she says, "it would seem as if the world's history were made only by the asylum and hospital, by neuropaths and epileptics and consumptives." The last statement is rather strong, but there is some basis for it.

The drugs bringing genius to disaster which are particularly discussed are alcohol, opium and chloral, and the disease toxin, that of tuberculosis. These agents are supposed to act chiefly by temporary relieving genius from the inhibitions imposed by the training of the civilized life, the intoxication of drugs and disease poisons breaks down inhibitions and releases genius if it exists.

The author differentiates the effects of alcohol and opium as observed in the productions of genius. Alcohol gives "pictures sharp and distinct", with opium are observed "alliteration, shifting and drag of attack, of plan, of purpose, of setting, of character, the syncope, the phantasmagoria and hallucination." She claims that it is easy to detect from examination of the work itself which drug was used.

She cites a few well known writers as shining or horrible examples, as follows. De Quincey took opium in large quantities, but as he took it in the form of laudanum and raised his daily dose as high as eight thousand drops of that preparation, he must at times have taken a great deal of alcohol also. Poe notably exemplifies the effects of opium. The author speaks of the "sonorous emptiness of Poe's Raven." Poe also took alcohol, but could not stand much of it. Coleridge took opium and his writings show marked evidences of its effects. Rossetti became a slave to chloral, having taken it at first for insomnia. It did not seem to have any noticeable effect on the quality of his work. James Thomson was a periodical drinker, and probably also took some opium, his work may be generally considered to illustrate the workings of genius under the influence of alcohol, but in spots according to the author it shows evidences of opium. Stevenson's case shows how the poison of tuberculosis can stimulate or facilitate the productive activity of great genius. Swinburne is considered to be hysteric if not epileptic. Nietzsche's stigmata of insanity are referred to, and also Strindberg's. The studies given of Poe and James Thomson are particularly keen, sympathetic and interesting.

There is no notice in this book of coffee, which in moderate doses excites the higher brain centres and may increase the rapidity if a dose does not improve the quality of the mental processes, but which in excessive doses causes confusion of thought, which drug is probably used by the literary tribe more than all others combined to lash Pegasus. Nor is any reference made to that greatest of all literary geniuses, in whose writings can be found no stigmata of any kind, and who himself observed that great wit to madness is often near allied.

This is a clever, a brilliant essay, and will interest many.

NEW YORK, N Y

JUNE 15, 1926

THE SYPHILIS EXHIBIT

*An editorial description of the exhibit conducted on Thursday, April 1, 1926,
the last day of the Annual Meeting of the Medical Society
of the State of New York*

AN all day exhibit covering all phases of a single disease has been adopted by the Medical Society of the State of New York as a feature of its Annual Meetings. The first exhibit, that of 1925, was on the subject of Tuberculosis. That of 1926 was on Syphilis.

The Syphilis Exhibit was probably the most comprehensive and complete that was ever attempted on that subject, and its influence on the audience was bounded only by the physical limitations of time and exhibit space, and the retentive powers of the observers. All phases of the medical problem of syphilis were shown in graphic form—clinical cases, pictures, charts, pathological specimens, books, movies, lantern slides and lecturers. Above all, there was a deeply interested audience of over five hundred physicians, about one hundred of whom came especially to see the exhibit.

All the features were assembled, set up, exhibited, dissolved and removed during the twenty-four hours, from midnight to midnight, of Thursday, April 1. To accomplish this takes required careful planning and prompt execution.

The exhibit was a part of the scientific program of the State Medical Society and was promoted by its Scientific Committee of which Dr Andrew Mac Farlane of Albany was Chairman. The immediate execution of the plans was placed in the hands of a local committee consisting of Dr Louis I Harris, Commissioner of Health of New York City, Dr Albert Pfeiffer, representing the State Department of Health, Dr Joseph S Lawrence, Executive Officer of the Medical Society of the State of New York, Dr William F Snow, Medical Director of the American Social Hygiene Association, Dr Walter Brunet, Dr Louis Chargin, Dr Howard Fox, Dr George M Mackee, Dr Alfred Potter, Dr Hans Schwartz, Dr Alec N Thomson and Dr Fred Wise.

The local committee held several meetings and decided on the exhibitors and speakers to be invited. It was planned to hold the exhibit in the

Waldorf-Astoria Hotel, New York, in the same rooms in which the regular meeting of the Society was held. The grand ball room and part of the second floor around it were given over to the exhibit. Booths were erected in the ball room itself, and the adjoining rooms were used for lectures and picture demonstrations.

The booths, 28 in number, were built especially for the occasion by S Asch, Exposition Builder and Decorator of 74 West 48th Street, New York, who has constructed the booths for the commercial exhibit of the State Medical Society for a number of years. The booths were made of large panels of beaver board, slid into grooved frames which were supported on light standards. The walls were about eight feet high and were plainly painted. The cost of the booths was something under six hundred dollars. They were built in units of standard sizes and all were erected within three or four hours time. The hotel workmen supplied the electrical connections at a cost of about sixty dollars.

An unusually large amount of material for the syphilis exhibit was available in New York City. Cases, specimens, pathological laboratories, clinicians and teachers—all were numerous. The Committee was hampered by the abundance rather than the scarcity of material. All phases of the problem of syphilis were illustrated in the exhibit. For the general practitioner of medicine cases of syphilis of almost every organ of the body were provided, and in many diseases there were also pathological specimens which illustrated the conditions with which the patients suffered. Laboratory workers were on hand to demonstrate microscopical and serological conditions. The Department of Health showed diagrams and charts illustrating how they dealt with the governmental phases of syphilis. Teaching problems were illustrated by medical schools and hospitals. Large organizations showed how they were educating the people regarding syphilis and providing literature and conducting cam-

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

- AVIATION MEDICINE.** By LOUIS HOPEWELL BAUER, A.B., M.D. Published by authority of the Surgeon General. Octavo of 241 pages, with illustrations. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$7.50.
- EVOLUTION, GENETICS AND EUGENICS.** By HORATIO HACKETT NEWMAN. Second Edition. Octavo of 639 pages, with illustrations. Chicago, University of Chicago Press, 1925.
- A HANDBOOK FOR SENIOR NURSES AND MIDWIVES.** By J. K. WATSON, M.D. 12mo of 554 pages with illustrations. New York, Oxford University Press, 1926. Cloth, \$4.00 (Oxford Medical Publications).
- A MANUAL OF CLINICAL LABORATORY METHODS.** By CLYDE LOTTRIDGE CUMMER, Ph.B., M.D. Second Edition, thoroughly revised. Octavo of 547 pages with illustrations. Philadelphia and New York, Lea and Febiger, 1926. Cloth, \$6.50.
- THE DIAGNOSIS AND TREATMENT OF TUBERCULOSIS OF THE HIP.** By G. R. GIRLESTONE, B.M. (Oxon.), F.R.C.S. Octavo of 94 pages, with illustrations. New York, Oxford University Press, 1925. (Oxford Medical Publications).
- SURGICAL CLINICS OF NORTH AMERICA.** Vol. 5, No. 6, December, 1925. (Philadelphia Number). Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper, \$12.00 net.
- HYGIENE OF SEX.** By MAX VON GRUBER. Authorized English Translation. 12mo of 169 pages. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$1.50.
- CHEMISTRY AND RECENT PROGRESS IN MEDICINE.** By JULIUS STIEGLITZ. Octavo of 62 pages. Baltimore, Williams and Wilkins Company, 1926. (The Johns Hopkins University School of Medicine, The Charles E. Dohme Memorial Lectureship, Second Course, 1924).
- FACTS ON THE HEART.** By RICHARD C. CABOT, M.D. Octavo of 781 pages with 163 illustrations. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$7.50.
- GASTRIC FUNCTION IN HEALTH AND DISEASE.** By JOHN A. RYLE, M.D., F.R.C.P. Octavo of 152 pages, with illustrations. New York, Oxford University Press, 1926. Cloth, \$2.75 (Oxford Medical Publications).
- VISUAL FIELD STUDIES.** By RALPH I. LLOYD, M.D., F.A.C.S. Octavo of 216 pages with 124 illustrations. New York, The Technical Press, 1926. (For sale by E. C. Swezey, 50 Pine Street, New York City). Cloth, \$6.00.
- YOUNG'S PRACTICE OF UROLOGY.** Based on a Study of 12,500 Cases. By HUGH H. YOUNG, M.D., and DAVID M. DAVIS, M.D. Two octavo volumes, totaling 1484 pages with 1,003 illustrations. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$25.00.
- GOULD AND PYLE'S POCKET CYCLOPEDIA OF MEDICINE AND SURGERY.** Based upon the Fourth Edition of Gould Pyle's Cyclopedia of Practical Medicine and Surgery. Third edition. Revised, enlarged and edited by R. J. E. SCOTT, M.A., B.C.L., M.D. 16mo of 922 pages. Philadelphia, P. Blakiston's Son and Company, 1926. Flexible binding, \$2.00, with thumb index, \$2.50.
- SIXTY YEARS IN MEDICAL HARNESS.** Or the Story of a Long Medical Life, 1865-1925. By CHARLES BEN EULYN JOHNSON, M.D. Octavo of 333 pages. New York, The Medical Life Press, 1926. Cloth, \$3.00.
- MEDICAL DIAGNOSIS FOR THE STUDENT AND PRACTITIONER.** By CHARLES LYMAN GREENE, M.D. Sixth edition revised and enlarged. Octavo of 1468 pages with 14 colored plates and 709 other illustrations. Philadelphia, P. Blakiston's Son and Company, 1926. Cloth, \$12.00.
- NOUVEAU TRAITÉ DE MÉDECINE.** Published under the Direction of G. H. ROGER, FERNAND VIDAL and P. J. TEISSIER. Fascicule XIX. Pathologie du Cerveau et du Cervelet. Octavo of 1016 pages, with illustrations. Paris, Masson et Cie, 1925. Boards, 75 francs.
- THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY IN THE WORLD WAR.** Volume VIII. Field Operations. Prepared under the direction of MAJ. GEN. M. W. IRELAND. By COL. CHARLES LYNCH, M.C., COL. JOSEPH H. FORD, M.C. and LIEUT. COL. FRANK W. WEEP, M.C. Octavo of 1097 pages, with illustrations. Washington, Government Printing Office, 1925.
- THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA.** Tenth Decennial Revision. By Authority of the United States Pharmacopoeial Convention, held at Washington, D. C., May 11, 1920. Prepared by the Committee of Revision and published by the Board of Trustees. Official from January 1, 1926. Octavo of 626 pages. Philadelphia, J. B. Lippincott Company, 1925.
- INTERNATIONAL CLINICS.** Volume 1. Thirty-Sixth Series, 1926. Octavo of 309 pages, with illustrations. Philadelphia and London, J. B. Lippincott Company, 1926.
- ARCHIVES OF THE ANDREW TODD MCCLINTOCK MEMORIAL FOUNDATION FOR THE STUDY OF DISEASES OF THE ALIMENTARY CANAL.** Volume 1. Pleomorphism in Bacterial Protoplasm. A study in Psittacosis. By ANDREW TODD MCCLINTOCK, M.D. Octavo of 240 pages. Privately printed, 1925.
- POTTER'S COMPEND OF MATERIA MEDICA, THERAPEUTICS AND PRESCRIPTION WRITING.** With especial reference to the Physiological Action of Drugs. Based on the Tenth Revision of the U. S. Pharmacopoeia including also many un-official remedies by A. D. BUSH. 9th Edition. 12mo of 262 pages. Philadelphia, P. Blakiston's Son and Company, 1926. Cloth, \$2.00.
- OPHTHALMIC NEURO-MYOLOGY.** A Study of the Normal and Abnormal Actions of the Ocular Muscles from the Brain Side of the Question. By GILES C. SAVAGE. Second Edition. Octavo of 227 pages, illustrated. Nashville, Tenn., McQuiddy Printing Co., 1926. Cloth, \$3.00.
- INDIGESTION.** What It Is and How to Prevent It. By ARTHUR L. HOLLAND. 12mo of 130 pages, illustrated. New York, D. Appleton and Company, 1926.

Skin and Cancer Hospital The doctors showed a special needle designed to prevent the seepage and extravasation which are the usual causes of the shock of spinal puncture

15 **Drugs and methods of Syphilis Therapy** used in the clinics of the Department of Health of New York City were shown by Drs L Chargin and A Stone

16 **Dr D Satenstein of the Vanderbilt Clinic** showed 25 microscopic slides of pathological specimens illustrating syphilis in its various stages and forms

17 **Radiograms of various manifestations of syphilis** were shown by Dr I S Hirsch of Bellevue Hospital

18 **Photographs and inoculated animals illustrating experimental syphilis** were shown by Drs Wade Brown and Hideyo Noguchi of the Rockefeller Institute

19 **The Wassermann test** was demonstrated by Dr A B Wadsworth of the Laboratory of the Department of Health of New York State

20 **Dr Kahn of the Laboratory of the State Department of Health of Michigan** gave vivid demonstrations of his new precipitin test for the detection of syphilis This was the outstanding new feature that was shown at the exhibit

21 **Drs A. Jacoby, W Seckel and M Nemer** of the Department of Health of New York City, showed living spirocheta under the microscope.

22 **Dr Howard Fox of the New York University** showed lantern slides illustrating syphilis among colored people

23 **Dr Emily D Barringer** brought women patients from the Kingston Avenue Hospital and demonstrated early syphilitic lesions of the vagina and cervix, dwelling especially on difficult points in diagnosis

24 **Dr H Winter** from the New York Dental College demonstrated methods of restoring the soft parts of the mouth following their destruction by ulcerative syphilitic processes He showed patients whose palates were almost completely gone and yet who were able to swallow and talk normally when the artificial palate was worn

25 **Mr Frank Place**, Assistant Librarian of the New York Academy of Medicine, showed representative publications on syphilis

26-28 **The New York City Department of Health, the New York State Department of Health and the American Social Hygiene Association**, each showed literature diagrams and charts illustrating methods of educating both the doctors and the people regarding syphilis

Papers which embody the talks given informally by the demonstrators have been prepared and are printed elsewhere in this issue of the JOURNAL

A program consisting of papers on syphilis was also carried out during the afternoon of the

day of the exhibit These papers are also published in this issue of the JOURNAL

A booklet on "The Fundamentals of Syphilis" was the special contribution of the New York State Department of Health to that part of the annual meeting which was devoted especially to syphilis This booklet was prepared under the supervision of Dr Albert Pfeiffer, Director of the Division of Venereal Diseases, and Dr Walter A Brunet of the American Social Hygiene Association A copy of it was mailed to every member of the State Medical Society It was designed to inform doctors in general practice regarding the modern standard of the diagnosis and treatment of syphilis While much of its matter is fundamental and is almost popular in style and contents, yet it does state simply and clearly the modern point of view which a doctor should have regarding the disease One who reads the booklet will refresh his memory in the essential points of the disease He will also find it to be a model form in which he may import information to his less informed colleagues and to his more intelligent patients. The booklet takes up the early diagnosis of the disease, especially in its early stages, by the recognition of the causative agent, the *Spirocheta Pallida*, and says

"No physician, and no hospital or dispensary which is not equipped to identify the organism of syphilis or is unwilling to see that the patient gets the benefit of such knowledge elsewhere if it is called for by the nature of his case, has any right to pretend to deal with early syphilis

"The constitutional effects of secondary syphilis are not limited to the skin and the mucous surfaces of the mouth and genitals, but there are in about half of the cases well-defined constitutional symptoms It is these cases which have severe and early recognizable symptoms that most often go early to a physician, and fortunate it is for them as it places them immediately under medical supervision On the other hand cases which have slight symptoms or none at all come under the physician's care late and in these cases it so often happens that the delay is often a cause for grave cardio-vascular and other visceral changes which may become apparent later or only at a post-mortem Syphilis in its early local and secondary stages is usually one of the mildest of all the serious infections as far as symptoms are concerned In its later stages it is without a peer one of the gravest disease entities"

The two principal diagnostic tests, the recognition of the spirocheta and the Wassermann reaction, are given and syphilis in pregnancy is described, and finally, the standard therapeutic measures are outlined

The general practitioner should find the book of real value in assuring him that he is following the accepted standards when he examines and treats a patient for suspected syphilis

paigns for better laws. The New York Academy of Medicine had a table full of representative books on the subject of syphilis.

The material for the exhibits were sent to the hotel on the previous day so far as possible and each exhibitor made his own arrangements for the transportation and care of his exhibit. Cases were brought to the hotel on the morning of the exhibition and those who remained during the noon hour were given a lunch.

The State Medical Society had appropriated one thousand dollars for the expenses of the exhibit and the total expenses came within that sum. A liberal policy was adopted in regard to such items as the cost of transporting and feeding patients, for hospital and colleges often had no funds for those purposes. The cost was remarkably low considering the necessary rapidity with which the exhibit had to be assembled and dispersed.

While the formal exhibits numbered twenty-eight, an estimation of the number of experts taking part in them would be difficult. Certainly over one hundred physicians and laboratory workers were actively engaged on the exhibit.

It is quite difficult to estimate the number of patients shown, but there were at least one hundred.

The following is a list of the exhibitors.

1 Dr M Parounagian and F Mason demonstrated clinical syphilis in its primary and secondary stages on patients and photographs from Bellevue Hospitals.

2 Dr Benson Cannon demonstrated tertiary syphilis including leg ulcers and gummata on patients from the City Hospital.

3 Dr Dudley D Stetson showed the scars of healed lesions on cases from the New York Skin and Cancer Hospital.

4 Drs S Oppenheimer, B Crohn, A Winkelstein and J Marcus demonstrated syphilis of the stomach on patients from Mount Sinai Hospital.

5 Cardio Vascular conditions were demonstrated by Dr Harlow Brooks on patients from the City Hospital and on pathological specimens of organs which were affected like those of the patients. Especially striking was an immense aortal aneurism almost as big as a man's head, and a patient who had a similar aneurism almost as large and yet he could go about and do light work. Dr Brooks also showed specimens of hearts whose cut surfaces were spotted with small white areas of syphilitic degeneration. The patients had died suddenly and the only lesions found were those in the heart.

6 Pulmonary syphilis was illustrated by patients and X-rays shown by Dr G Ornstein from the Vanderbilt Clinic.

7 Patients and X-rays illustrating bone and joint syphilis were shown by Drs S Kleinberg, J Buchman, R Kahle and P Colonna, from the

New York Hospital for the Ruptured and Crippled.

8 Pathological specimens, including lantern slides, of cerebrospinal syphilis were shown by Drs I Strauss and J Globus from Mount Sinai Hospital.

9 Patients suffering from Tabes were shown by Drs M Keschner and M Grossman from Mount Sinai Hospital.

10 The subject of Paresis was illustrated with cases from the New York State Psychiatric Institute by Drs G H Kirby and A Pollack.

11 Dr Arthur S Tenner, of New York, exhibited cases of syphilis affecting the anterior segment of the eye. The patients were from the clinics of the Post Graduate Hospital. Five cases of interstitial keratitis in various stages were shown. Four of these were due to congenital syphilis and one, aged 27, a monocular case, was due to acquired syphilis. Of the congenital cases, only one showed the typical facies of congenital lues, the saddle back nose and rhagades. As he was only 5 years old, with permanent teeth unerupted, of course there were no Hutchinsonian teeth. The other congenital cases all showed moderate modifications of the central incisors of the Hutchinsonian type.

Cases of irido-cyclitis of syphilitic origin were also shown.

Despite the current belief that the doctor in general practice is indifferent in ophthalmological matters, Dr Tenner was extremely gratified by the interest shown by his numerous auditors both in the cases and his demonstration.

In the afternoon, Dr M Uribe Troncoso gave a demonstration of several patients with luetic involvement of the fundus of the eye. Using the electric ophthalmoscope of a new and powerful model, he demonstrated cases of atrophy of the optic nerve, primary and secondary to neuritis and chorioretinitis in acute and chronic stages.

Dr Troncoso also gave a lecture on syphilitic fundus diseases, throwing on the screen slides showing the conditions that can be found in the syphilitic infection of the inner eye structures.

12 Patients showing syphilitic lesions of the auditory nerve were shown by Dr R Almour of Beth Israel Hospital.

13 Dr I Rosen from the Vanderbilt Clinic and Dr S Sherwood from Mount Sinai Hospital showed patients suffering from congenital syphilis, and gave demonstrations of the technique and methods of therapeutic measures by actually treating the cases and taking their blood for diagnosis.

14 Early Neuro-Syphilis was demonstrated by Drs Randal Hoyt and A MacGregor of the

appearance and the involvement of the temporal and occipital regions are quite diagnostic

15 Secondary Syphilis, with a interesting history, was first seen on Jan 14, 1926, who had a frenal sore of 3 weeks duration. He was treated by a private physician with salves. Five dark-field examinations were negative and his Wassermann test as late as March 15, 1926, was negative

Roseola appeared on March 10, 1926

This case conclusively proves that, *we must not treat suspected lesions with any kind of applications but saline solution, until a diagnosis is made*

16 Gumma of the Scrotum (right), aged 44, colored. Ulceration of Mouth and Tongue. Scar of Chancre on dorsum of penis, 8 months previously. Phimosis, Gummatous ulcer on thigh. Secondary stage but tertiary lesions

17 Charcot-Joint (left knee), patient aged 43, infection 23 years previously. Duration was over one year. The Wassermann was + repeatedly

18 Charcot-Joint (left knee), Italian, aged 51, infection 18 years, Wassermann +, diagnosis confirmed by the X-ray examination

19 Rosette Type of Chancre, colored, age 19, exposed 3 months previously. Annular Syphilide of naso labial junction, Wassermann reaction +. Condylomas about the anal regions. This type of lesions nearly diagnostic of syphilis

20 Lip Chancre (upper and lower). Roseola. His Wassermann examination was reported +

21 Syphilitic Alopecia, aged 26, multiple chancres three months. Syphilitic Leucoderma. Prior Incubation period two weeks

22 Gumma of the Meatus, Syphilitic Orchitis, Scar of Old Chancre on Glans Penis. Colored, aged 23. He gave a history of chancre 6 years previously. His last exposure was 6 months since Wassermann +. Dark-field negative. Duration 6 weeks

23 Meatal Chancre, Fading Roseola. Wassermann +, dark-field positive. Meatal sores with few exceptions are of syphilitic origin

24 Chancre of the Eyebrow (right), aged 22 chauffeur. The lesion was nearly healed. He was shown with his photo

25 Anal Chancre, Congenital Signs of Syphilis. A youth of 17 yrs, admitted perversion. His Wassermann was + and had marked secondaries. The anal infection usually detected from the swelling of the lymphatics below the Poupert's ligament

4 Gumma of chin, Showing result of treatment

5 Congenital Syphilis, Hutchinson's Teeth (Female)

6 Congenital Syphilis, Hutchinson's Teeth, (Male)

7 Alopecia Syphilitica. (Female)

8 Alopecia Syphilitica, Result of Treatment

9 Alopecia Syphilitica (male)

10 Alopecia Syphilitica, Result of Treatment

11 Annular-Pigmented Syphilide in a white woman (not very common)

12 Nodular Syphiloderm of Chest, Ulceration of Pubic region with complete destruction of penis

13 Congenital Syphilis, showing a well marked example of Tubercle of Mibelli. This boy's parents and a younger brother were patients of ours

14 Gumma of the inner canthus

15 Result of Treatment

16 Condyloma of the groove of the chin (quite uncommon)

17 Chancre of Upper Lip (moustach region)

18 Lip Chancre (upper), unusually large and resistant to treatment. This was an extra-marital infection, who later infected her husband

19 Epithelioma of the lower lip, resembling chancre, in a syphilitic

20 Multiple Chancres, from one exposure, five in number, 2 on upper lip, 1 on lower lip, 1 on the abdomen near the pubic region and 1 on shaft of penis. Dark-Field was positive on all sores and marked roseola

21 Extensive gummatous ulceration of scrotum (rather rare)

22 Meatal Chancre, often diagnosed as gonorrhoea

23 Papulo-Squamous Syphilide, which could be mistaken for psoriasis

24 Extensive Condylomas of the Genitals

25 Lip Chancre (upper), unusually large, female

26 Gumma of the nose (gangrenous)

27 Result of treatment (no signs of scar)

28 Gumma of the naso-labial region

29 Congenital Syphilis, showing Hutchinson's Teeth (colored girl)

30 Chancre of Lip (lower), male

31 Perforating Ulcer of Foot

32 Double Chancre of Vulvae

33 Lip Chancre (lower), male

34 Lip Chancre (lower), female

35 Gumma of Scrotum, very extensive, left testicle exposed

36 Gumma of the Neck

37 Chancre of the Coronary Border

38 Multiple Chancres, two on glans penis and one on prepuce

39 Circinate Syphiloderm of the scrotum (tertiary)

40 Double Chancre of Vulvae, extensive condylomas in a colored child of 6 years

Parounagian Collection

1 Lip Chancre (upper). Husband had mucous patches on his tongue.

2 Gumma of the forehead

3 Gumma of chin, caused by a human bite

DESCRIPTIONS OF THE EXHIBITS

PRIMARY AND SECONDARY SYPHILIS

By M PAROUNAGIAN, M D, and F MASON, M D

BELLEVUE HOSPITAL, NEW YORK

THIS exhibit was conducted at the request of our very able Commissioner of Health, Dr Louis I Harris, to whom we are indebted for leadership in this important educational campaign

In our presentation of both the patients and photographs, we endeavored to demonstrate the common features as well as rarer phases of the disease, from the primary to the congenital stage

We presented twenty-five patients of which ten were female and fifteen male. A brief detailed outline will be given to bring out the essential points

One hundred and ten photographs of interest were posted on the walls illustrating many unusual forms of syphilis, a complete list of which will be included with comments on some of the interesting ones

The female patients presented the following conditions

1 Chancre Roseola (upper lip) a married woman, aged 26 years. Duration since February 1, 1926. On February 15, she consulted a physician who diagnosed it as "cold sore." This is a quite common diagnosis. This type of cases we seldom get before they have secondaries and 4+ Wassermann. Fortunately her husband was not infected. In this connection would say that, we have never encountered a second case of lip chancre in the same family

Marked swelling of the lymphatics corresponding to the location is a diagnostic sign

2 Gummatous Ulceration, with destruction of the soft palate in a young colored woman. Wassermann +

3 Congenital Syphilis, presenting a well marked example of tubercle of Mibelli, girl of 18 years, whose mother had died in an insane asylum. Her Wassermann test was +, had interstitial keratitis, high vault, imperfect hair line and a protruding forehead

4 Congenital Syphilis presenting a typical saddle nose, corneal opacity, + Wassermann and other signs confirming the diagnosis

5 Extensive Gummatous Ulceration of both legs of five years duration, a young woman who had been treated with salves only for a long time. This patient has a boy of 5 yrs with marked sign of congenital syphilis. Her Wassermann test showed + and she is getting well under anti-syphilitic medication

6 Leucoplakia in a marked Tabetic. This patient had marked Rhomberg, absent knee-jerks, fixed pupils and + Wassermann reaction. Leu-

coplakia is a very uncommon condition in women. This is the second case in a woman we have seen. She was a smoker

7 Congenital Syphilis, showing a typical example of Hutchinson's teeth. This patient had a positive family history and signs of congenital syphilis and also + Wassermann reaction

8 Secondary Syphilis with a profuse roseola, nothing unusual

9 Charcot-Joint, patient had been infected many years since and the duration of joint affection was said to be about two years. She showed unmistakable signs of tabes dorsalis

10 Extensive Circinate Rupial Syphilide of the back (tertiary)

The following were the male patients

11 Chancre of Frenum, the incubation was ten days, the lesion had been Roseola, Inguinal Bubo cauterized (poor technic) as the result of which three dark-field examinations were negative. Finally we secured positive dark-field and Wassermann. In this connection, we wish to state that nearly all frenal sores are of syphilitic origin

12 Syphilitic Super-Infection. First infection, March 5, 1925, he then had a chancre on the dorsum of prepuce, roseola and + Wassermann. Treatment from March 5th to May 19, 1925, he received 8 silver-arsph and 11 mercuric salicylate injections and discontinued treatment of his own accord

Returned Aug 10, 1925, with a Recurrent Roseola, Wassermann +

This time, received 6 arsphenamin and 15 mercury injections

On March 8, 1926, returned with a typical chancre on the ventral aspect of shaft (middle) and two small lesions on the left side of scrotum. He had been exposed one month prior to the appearance of the new lesions

The dark-field examination from all three lesions were positive. He again presented a marked roseola and his Wassermann test was +

13 Congenital Syphilis, a boy, aged 12, referred to us from the Eye department of Bellevue Hospital. He presented a tubercle of Mibelli, high arch, interstitial keratitis, etc. He had repeatedly positive Wassermann

14 Syphilitic Alopecia, Fading Roseola, Mucous patches in throat. This condition usually met at the early stages, most often within six months after the infection. It is claimed that alopecia of this origin usually occurs in patients who have had febrile onset. The "moth eaten"

old He entered the hospital six years ago complaining of pain in the pit of the stomach which came on a few hours after meals and was relieved by taking food The radiographer suspected peripyloric adhesions The Wassermann reaction was 4 plus He had a profound anemia of the primary type and low acid figures in the stomach He left the hospital against advice after a very brief course of anti-luetic treatment Five years later, last August, he again entered the hospital with the same complaints The findings then were a profound secondary anemia, 4 plus Wassermann reaction, a true achylia gastrica, and the radiograms showed a large irregular filling defect in the posterior wall of the stomach near the cardia Malignancy or gumma of the stomach were considered as possible diagnoses Due to the great operative risk, he was placed on anti-luetic treatment As you see, these X-ray films showed no change in the lesion after a few weeks of treatment However, the last films, taken after five months of treatment, show an almost complete disappearance of the defect, only a slight irregularity of the posterior wall remaining visible in the oblique position The patient is obviously well-nourished, his anemia is now only moderate, and he has an excellent appetite and does not complain

It is true that we have no conclusive proof that this is gastric lues and it is also true that a 4 plus Wasserman reaction does not mean that an organic gastric lesion is luetic, yet this case seems to fulfill most of the necessary conditions (1) he has a positive Wassermann reaction, (2) achylia gastrica, (3) a defect and an anemia which would lead one to expect more cachexia if it were malignancy, (4) symptoms of ulcer rather than carcinoma, (5) a long duration with good appetite and a well nourished state, (6) a de-

crease in the size of the lesion under anti-luetic treatment

Let us leave the living case and pass on to view the specimen which, we might assume, represents the gross appearance of the patient's lesion The first jar shows a large gumma, lemon size, in the posterior wall of the stomach This patient had vomiting and epigastric pain for one year, and died of a peritonitis which followed a gastro-enterostomy He also had, as seen in the second jar, a luetic liver or *hepar lobatum* In the third jar, you will see another stomach which shows a diffuse nodular ulcerated infiltration in the pyloric end of the stomach This specimen was obtained from a boy 19 years old who died one week after a subtotal gastrectomy The autopsy showed in addition syphilis of the aorta and myocardium.

The microscopic preparations, photographs and lantern slides reveal the characteristic histologic lesions of tertiary syphilis (1) diffuse submucosal infiltration—chiefly plasma and lymphoid cells, (2) miliary gummata—with multi-nucleated giant cells and plasma cells, (3) vessel involvement—peri-vascular infiltration with round cells, endarteritis and endophlebitis obliterans The illustration on the wall is a micro-photograph of gastric syphilis which is the only case on record showing spirochetes (case published by McNee)

A presentation of this subject should not be closed without emphasizing the following features (1) the rarity of the disease, (2) the possibility of making clinical diagnosis, (3) the excellent results of treatment if prolonged and intensive, (4) an organic gastric lesion with a positive Wassermann is only rarely luetic, (5) and that the histologic features, and the response to anti-luetic therapy, as judged by careful X-ray studies, are the two best diagnostic criteria

PULMONARY SYPHILIS

By GEORGE G ORNSTEN, M D

DEPARTMENT OF TUBERCULOSIS VANDERBILT CLINIC COLUMBIA UNIVERSITY

THERE is no question as to the existence of pulmonary syphilis It is a rare disease but occurs more frequently than the pathologists report From their autopsy figures, one would believe that its occurrence is exceptionally rare as a "clinical entity" Fowler (1) found but twelve specimens in the museums of the London Hospitals and the Royal College of Surgeons Two of these cases were doubtful At the Johns Hopkins Hospital, Osler (2) reported 12 cases out of 2,800 autopsies Of these 12, only 4 were acquired Among 3,000 autopsies at the Massachusetts General Hospital, Lord (3) found only 1 case of acquired syphilis Symmers (4), in a study of 4,800 autopsy protocols, 314

of which showed lesions of syphilis, reported 12 cases and syphilitic pleural scars in 2 more Syphilis of the trachea and bronchi is perhaps a less rare condition Connors (5), in 1903 collected 128 cases Symmers (4) mentions 4 cases involving the trachea among 4,800 autopsies Lord (3) reported 2 cases in 3,000 autopsies at the Massachusetts General Hospital.

This difference between clinical impressions and the results of compilation of autopsy statistics may be accounted for by the hesitancy of the pathologists in making a diagnosis of syphilis of the lung MacCallum's (6) description of the tertiary stage of syphilis and how difficult it is to differentiate it from tuberculosis, especially in

- 41 Rupial Circinate Syphilide (generalized)
- 42 Secondary Syphilides of the Genitals
- 43 Palmar-Syphilide (Tertiary) As a rule unilateral
- 44 Tertiary Circinate Syphiloderm of Fore-arms
- 45 Palmar Syphiloderm (Secondary) Usually symmetrical
- 46 Phagedenic Chancre of Pubic Region and base of penis

- 102 Multiple Gummatous Ulcerations of both hands
- 103 Gumma of the Middle finger
- 104 Unusual Scar-Like Remains of Secondary Lesions, "Split-Pea Papules" at the angle of Mouth
- 105 Multiple Gummas of Body
- 106 Papulo-Squamous Syphiloderm (late secondary)
- 107 Roseola (Secondary)
- 108 Pustular Syphilide in a negro
- 109 Chancroid of Penis and Middle Finger (Auto-Innoculation)
- 110 Leucoplakia of Tongue

SYPHILIS OF THE STOMACH

By S S OPPENHEIMER, M D, B B CROHN, M D, A. WINKELSTEIN, M D, and J M MARCUS, M D
MOUNT SINAI HOSPITAL, NEW YORK CITY

SYPHILIS of the stomach is a very rare disease. It is estimated that it comprises less than one per cent of visceral lues. Hartwell believes that of 200 cases in the literature only 25 are authentic. We have been able to collect, in Mount Sinai Hospital, over a period of 25 years, only four instances. Of these, 3

were pathologically proved luetic, and one was a clinical diagnosis, presumably correct.

We are fortunate in being able to demonstrate to you (1) a clinical case, (2) two gross specimens and (3) radiograms, microscopic preparations, photographs and lantern slides.

The patient sitting here is a man, 38 years

fication of the breath sounds or rales heard. The heart was normal.

On questioning the patient he admitted a luetic history. His primary lesion occurred fourteen years ago. An X-ray was taken of his lungs. There was an exaggeration of the bronchial markings, especially in both roots and in the upper half of the left lung. Two sputa examina-

FIG. 1.—X-ray taken July 21, 1924. A parenchymatous infiltration extends out from both root regions to the bases of the lungs. The right lung is further complicated with a pleural effusion.

tions were negative for tubercle bacilli. His Wassermann was 3+. Tuberculosis was excluded because of his negative physical findings and a negative X-ray. Because of a similar experience with six other cases, syphilis of the trachea and bronchi was thought of. A tertiary syphilitic ulceration of the trachea or bronchi might easily account for the hemoptysis, the cough, and the expectoration. The mild toxemia might easily be due to his syphilis. The patient was sent to the service of Dr. Arrowsmith at the Kings County Hospital. There he was bronchoscoped by Dr. M. C. Myerson. At the Kings County Hospital he was X-rayed again. His Wassermann was also repeated. Their reports were as follows: "The Roentgen examination of the chest showed nothing abnormal. The Wassermann reaction was 4+."

Bronchoscopic study revealed the following: "On the anterior wall of the right main bronchus just beyond the carina there was an irregular swelling of moderate degree. This area was dark red in appearance, while the remainder of the bronchus appeared darker red than normal."

This area of swelling was not obstructive. It measured approximately $1\frac{1}{2}$ cm. in length and 5 mm. in width. There were two distinct white areas of ulceration, irregularly round, about 3 mm. in diameter, and situated upon this area of swelling. In the left main bronchus, just at the carina, there was a similar small ulcer surrounded by an area of redness, situated upon the anterior wall. The diagnosis of gumma of the bronchus with beginning ulceration was rendered. Since his bronchoscopic examination the patient improved after a course of salvarsan therapy. On November 1, 1924, his Wassermann was again 4+. He again expectorated some blood. Another course of salvarsan therapy helped. An X-ray taken on March 29, 1926, showed no evidence of pulmonary tuberculosis. (Patient under observation from February 12, 1925, to March 29, 1926.)

Discussion.—The above case and the six others reported in 1924 gave almost a uniform history. Hemoptysis accompanied by cough, expectoration, loss of weight, and symptoms of a mild toxemia were the chief complaints. A picture of pulmonary tuberculosis was presented to the examiner. The negative physical and X-ray examination suggested an early pulmonary tuberculosis. The pathology was apparently not extensive enough to produce either physical findings or X-ray shadows. There are such cases of pulmonary tuberculosis in which the physical findings and Roentgen markings appear two or

FIG. 2.—X-ray taken on August 20, 1924. There is an extension of the lesion over the left base. The pleural effusion is still present.

the lungs, may be a good explanation for syphilis of the lung being so rare an autopsy finding

The clinical picture of pulmonary syphilis is not characteristic. The symptoms simulate those of pulmonary tuberculosis, and, as a rule, a diagnosis of early tuberculosis is made. The cases referred to the clinic were all suspected to be tuberculosis.

I have the pleasure of presenting for your consideration a case of secondary syphilis of the trachea and bronchi simulating asthma, one of tertiary syphilis of the trachea and bronchi, and one case of tertiary syphilis of the lung.

SYPHILIS OF THE TRACHEA AND BRONCHI SIMULATING ASTHMA

Case 1—M S, colored, male, age, twenty-nine years, came to the clinic December 1st, 1924.

History—He complained of wheezing attacks that kept him awake at night. He also felt warm in the afternoon. Because of the wheezing and shortness of breath he has not been able to carry on his usual trade of shoe repairing. Last August he was well. At that time he had a skin eruption which was diagnosed as a syphiloderma. He was not sure when he had his chancre. He thought he might have acquired it with a gonorrhea two years ago. In August, after the appearance of the rash over his body, his Wassermann was 4+. Four weeks after the appearance of the rash he was seized with wheezing attacks which have persisted up to the present date. On admission his temperature was 99°F, pulse 80, respirations 24.

Physical Examination—Loud, large, sonorous sounds were heard over both lungs. His heart was normal.

X-Ray Examination—Except for an accentuation of the bronchial markings, the lungs were normal.

The skin of his whole body showed a brownish, coppery mottling with slight scarring, probably the remains of a macular-pustular eruption. On examining his mouth, over the left buccal mucosa there was a mucous plaque about the size of a twenty-five cent piece. There was congestion of the pharyngeal and palate structures. The uvula was very congested and had an appearance similar to a mucous patch without the sloughing. The late Dr. John A. Fordyce and Dr. Fred Wise called it a "syphilitic angina" of the pharynx. With such pathology in the mouth and pharynx we thought we might be able to explain the sudden appearance of these wheezing attacks to a similar condition in the trachea and bronchi. We referred him to the bronchoscopic clinic of Dr. M. C. Myerson at the Beth Israel Hospital with a diagnosis of syphilis of the mucous membrane of the trachea and the bronchi, causing asthmatic attacks.

Dr. Myerson's report was as follows: "On the

left buccal mucosa there was a mucous plaque about the size of a twenty-five cent piece. There was an acute congestion and slight edema of all the pharyngeal and palate structures. The palate showed several small macular lesions. His larynx showed the same type of involvement as his pharynx. The bronchoscopic findings were as follows: The tracheal and bronchial walls in their non-cartilaginous portions were the seat of the same type of congestion and edema as the structures just mentioned. The mucosa in the cartilaginous portions of the trachea and bronchi showed slight capillary prominences here and there, with an increased redness of the mucosa. On the anterior wall of the right main bronchus, about 15 mm from the bifurcation of the trachea, an irregularly crescentic white area was seen. This could not be wiped away, nor could it be removed by suction, and was identical in appearance with the mucous plaque observed on the buccal mucous membrane. The buccal plaque was observed through the same bronchoscope for comparative study, in this way the similarity of the lesions was definitely established."

The patient was placed on intensive antiluetic therapy. There was an immediate clearing up of his asthma. The patient felt so well he decided he did not need any more therapy. He went back to his shoe repairing. Two months later he returned to the clinic complaining of asthmatic attacks. His Wassermann was again 4+. He was placed on intravenous injections of salvarsan, with marked improvement of his asthma.

DISCUSSION—Osler (2) in his discussion of secondary syphilis mentions the frequency of catarrhal bronchitis as a complication. Perhaps the above case explains this acute catarrhal bronchitis, the eruption in the mucous membrane of the trachea and bronchi being less than occurred in the case reported. A similar condition frequently occurs in the exanthematous diseases and, perhaps, in a similar way one may explain the catarrhal bronchitis which frequently complicates measles and scarlet fever.

SYPHILIS OF THE TRACHEA AND BRONCHI SIMULATING PULMONARY TUBERCULOSIS

Case 11—A J, male, white, thirty-eight years old, came to the clinic February 12, 1925.

History—He complained of a cough for the last two years. Two years ago he had coughed up ½ ounce of blood. On January 3, 1925, he again coughed up ½ ounce of blood. His sputum was blood streaked for a few days following the hemoptysis. He complained of cough, expectoration, loss of weight, night-sweats, and malaise. On admission to the clinic his temperature was 98°F, pulse 68, and respiration 20. His weight was 126 lbs.

Physical Examination—There was no modi-

patient was X-rayed. The X-ray ruled out a tuberculous process. It showed an infiltration of the bases of both lungs with a pleural effusion over the right base. The possibility of a basilar tuberculosis was thought of. I have never seen such a condition without an apex being involved. To make sure we were not dealing with

FIG. 5—X-ray taken January 6, 1925. There is no evidence of the previous lesion.

a tuberculous process, a specimen of sputum was examined each day for a week. They were all negative for tubercle bacilli.

On August 11, 1924, the physical findings were unchanged. Her temperature varied between 99.6° F and 100.2° F. On August 20, another X-ray was taken because of the persistent findings. This X-ray showed an increase in the markings at the left base. The density of the shadows was also increased. Very little attention had been centered on the heart shadow. It suggested the possibility of an aortitis. The increase in X-ray shadows and the aortitis made us suspicious of syphilis. A Wassermann was taken and reported 4+. It was repeated and again reported 4+. The patient was placed on mixed treatment on August 27, 1924. Her temperature was 100° F, pulse 92, respirations 21, and weight 135¼ lbs. On September 3, 1924, her temperature was 98.4° F, pulse 80, respirations 24, and weight 135½ lbs. On September 5, 1924, the patient was given salvarsan therapy. There was an immediate improvement in her symptoms. The physical signs began slowly to disappear. The X-rays that followed showed a

gradual disappearance of the lesion. On January 1, 1925, her temperature was 98.6° F, pulse 90, respirations 24, and weight 151½ lbs.

Physical examination—No modification of breath sounds or rales were heard. On June 1, 1925, her temperature was 99° F, pulse 80, respirations 24, and weight 154 lbs. Physical examination. No modification of breath sounds or rales were heard. Examination, March 29, 1926. No modification of breath sounds heard over either lung. X-ray examination confirmed above impression. Her temperature was 98.8° F, pulse 96, respirations 24, weight 160½ lbs.

Discussion—This case is interesting because it was incorrectly diagnosed at first. The patient was ill for three months with cough, expectoration, fever, and all the signs of toxemia. She was then sent to the Vanderbilt Day Camp and placed on rest treatment. Under such routine treatment for three months there was no abatement in the symptoms except for a slight increase in weight. It may be argued that the patient had an intercurrent infection superimposed on a luetic condition. Such a process would not probably last six months. And, again, it may be noticed that an increase occurred in the X-ray shadows of the left lung between July 21 and August 20, 1924. The greater density in the X-ray shadows can be interpreted only as an increase in the pathologic process. It resembled closely the increase in shadows as occurs in malignancy of the lung. After the diagnosis of syphilis was made and the proper treatment instituted, not only the symptoms and physical signs but also the X-ray shadows disappeared. There was some suggestion that spirochetosis may have been the pathology in the lung, that frequently such a condition might produce a 4+ Wassermann. In this case, after the first course of treatments with salvarsan, her Wassermann became negative. Six months later it again became positive in spite of the fact that her lungs showed no pathology. She, therefore, must have syphilis and it is the latter disease which produced the 4+ Wassermann. Smith at Ray Brook had no positive Wassermann reaction in his 23 cases of spirochetosis. At no time were any spirochete demonstrable in her sputa.

It is therefore my opinion that we were dealing here with a case of syphilis of the lung.

three months following a history that is suggestive of the disease. In the above cases the history of lues with a positive Wassermann reaction threw a different light on the diagnosis.

FIG 3—X-ray taken September 19, 1924—sixteen days after antiluetic therapy had been instituted. The pathologic shadows are beginning to clear.

We may summarize as follows. A history of hemoptysis, cough, expectoration, etc., in the face of a normal lung condition, as demonstrated by physical and X-ray examinations, should suggest a possible syphilitic ulceration of the trachea and the bronchi.

TERTIARY SYPHILIS OF THE LUNG

Case 111—E D, female, colored, thirty years of age, came to the Vanderbilt Clinic, June 6, 1924 (See Figures 1 to 5).

History—She had been ill for the past three months, complaining of a continuous cough with a moderate amount of expectoration. She has had night-sweats and felt feverish in the late hours of the day. She was tired easily. She also complained of vague pains in her chest, especially over the sternum. She lost 13 lbs in weight in the last six months. Her chief complaint was cough and expectoration over a period of three months. Her temperature on admission was 100° F, pulse 104, respirations 24. Her weight was 128 lbs. She was referred from the Medical Department as a case of pulmonary tuberculosis. This diagnosis was confirmed because of the physical findings in the right upper lobe and a pleural effusion over the right base.

Physical Examination—Right lung. On per-

cussion there was flatness elicited below the ninth vertebral spine posteriorly and the fifth rib anteriorly. On auscultation, bronchovesicular breathing was heard from the apex to the second rib anteriorly and to the fifth vertebral spine posteriorly. A few moist rales were heard in this area. Over the area of flatness breath sounds were absent. Posteriorly, below the eighth vertebral spine, many moist rales were heard. Left lung. Anteriorly, between the fourth and sixth ribs, showers of moist rales were heard.

A needle was inserted into the lower right chest posteriorly and 10 cc of a clear straw-colored fluid withdrawn.

A diagnosis of pulmonary tuberculosis was made, complicated by a pleural effusion. The patient was referred to the Vanderbilt Bay Camp where she was put under the routine treatment for tuberculosis. Three days later her temperature was 99.2° F, pulse 104. The findings were the same except for a clearing up of the rales over the right apex. In the following month she was examined seven times. The physical findings never varied. Her temperature ranged between 99° F and 100° F. She added 3 lbs to her weight. Her cough and expectoration were not relieved. We still thought we were dealing with a tuberculous process. On July 21, 1924, the patient was examined again. The persistence of moist rales over the right base posteriorly suggested a bronchiectasis and a question of doubt as to tuberculous etiology. The

FIG 4—X-ray taken November 19, 1924—seventy-seven days after antiluetic therapy had been instituted. There is almost a complete clearing of the lesion.

popularized a system of co-ordinating exercises, in which vision is substituted for the disturbed postural sensibility, for the direction of movements. Moderate success was obtained with the use of this method.

Maloney in 1913 published a method that he had elaborated which was based on the following principles (1) Perfect thinking is essential to perfect moving, therefore training in perfect thinking is equivalent to training in perfect moving (2) Psychological as well as physiological elements are contained in all disabilities, this is especially true of tabes, and its treatment should be guided by the relation of these two components (3) The deterioration of attitude in tabes is due to both anatomical as well as mental factors (4) Blindfolding increases the ability to concentrate by eliminating external distraction (5) Relaxation or rest exercises tends to overcome fear states and allows the patient to recuperate quickly after exertion (6) Mechanical appliances as shoes, plates, and foot braces, used temporarily, aid in stabilizing the patient's attitude

To apply Maloney's method, one first teaches the patient to relax in a recumbent position. The patient is blindfolded and taught diaphragmatic breathing and by means of passive movements muscular relaxation is induced. This is followed by the simplest type of movement that can be done at any joint. The movement is first performed for the patient, next the patient attempts to do the movement guided by the physician, then the same movement is done without guidance, and finally the movement is done against resis-

tance. These simple movements are followed by more complicated ones, always done in the order outlined above. Fatigue must be avoided and periods of relaxation should follow each few minutes of active work. When the patient is able to perform all movements co-ordinately in the recumbent position, he is taught to balance and later to creep on his hands and knees. Next balance and progression on the knees alone is practiced, and finally balance in the upright position and walking are attempted. Each step must be taken slowly and only when all of the preceding exercises can be done perfectly without undue fatigue. The mechanical appliances are of great aid in stabilizing the patient's attitude. Re-education of the faulty postural sensibility is done by means of passive movements at the various joints. Postural sense is usually first and most profoundly affected in the smaller joints. It is therefore best to begin re-education in the larger joints and proceed to the smaller ones. Movements, on the other hand, should be started in the smaller joints first. When the patient is able to walk well under protected surroundings he should be taken outdoors and allowed to practice in a secluded place and as he gradually becomes more confident in himself he should be allowed to walk among crowds and under ordinary street conditions.

With this method of treatment I have been able to correct moderate degrees of ataxia in from six to eight weeks. More severe grades of ataxia require longer periods to correct. Even bedridden patients have regained their ability to again walk in public.

THE LABYRINTH TESTS AS AN AID IN THE DIAGNOSIS OF SYPHILIS OF THE CENTRAL NERVOUS SYSTEM *

By RALPH ALMOUR, M D

NEW YORK CITY

THE onset of neurosyphilis is insidious in the great majority of instances. Once established, it may exist for a greater or lesser period of time without producing clinical evidence of its presence. It is during the period of general dissemination of the spirochaetes that the central nervous system is invaded, and during this time headache, pains and vomiting may occur. These symptoms referable to the nervous system are in reality due to the general intoxication which is present and not to organic nervous lesions. They soon disappear, and although the presence of neurosyphilis may be demonstrated in the spinal fluid examination, the disease does not make itself clinically evident until very much later.

I desire to report the results of the functional examination of the ear in cases of neurosyphilis and to present the abnormalities that were found

to exist in the great majority of cases examined. Certain abnormalities appeared with such regularity that I am reporting them as a diagnostic aid.

The types of cases examined fell into three groups: those which had no symptoms referable to the ear, those having a complaint of deafness; and those suffering had no apparent or real loss in hearing but who complained of tinnitus.

The first group of patients comprised twenty cases of neurosyphilis—six cases of tabes dorsalis, eight cases of early paresis and six cases diagnosed as tabo-paresis. They were examined through the courtesy of Dr Oscar Levin of the Skin Clinic at Beth Israel Hospital. All showed on examination of the hearing with the tuning forks a distinct shortening of the bone

* From the Otolaryngological Department of Beth Israel Hospital, New York City.

EXHIBIT OF THE NEW YORK STATE HOSPITAL COMMISSION

By H M POLLOCK, M D,

ALBANY, N Y

THIS exhibit consisted of a series of charts and maps and was devoted entirely to neurosyphilis. The geographical distribution of general paralysis in the State was shown by a map in colors comparing rates of general paralysis first admissions to the civil State hospitals from the several counties of the State in 1925. That a wide difference in rates exist in various sections of the State was clearly demonstrated. This would imply that syphilis is also more prevalent in the counties showing high rates of general paralysis. The map was accompanied by a chart comparing the rates of general paralysis first admissions to hospitals for mental diseases in the several states of the Union in 1910 and 1923. In most of the states the 1923 rates were the higher but in New York State a significant decline in the rate has occurred since 1910.

More detailed information concerning variations in rates in recent years in New York State was shown by a chart giving the annual rates of first admissions with general paralysis to the State hospitals from 1911 to 1925. The chart shows that there was a gradual increase in the rate from 1911 to 1918, and that since 1918 there has been a general decline in the rate. The rate for 1925 was lower than that of any preceding year. An accompanying chart compared the rates per 100,000 of population in the several classes of cities and in rural districts. The chart covered admissions for the five years from 1915 to 1920. The highest average annual rate was found in first-class cities, 10.6, and the lowest in rural districts, 2.9. The general average annual rate for the whole State was 8.7.

Further analysis of rates given in a chart dealing with nativity and race of first admissions with general paralysis in the United States and

New York State showed that the lowest rates are found among the native white population of native parentage, and that much higher rates are found among the foreign-born white. The highest rates of all are found among negroes in New York State, the rate being 36.6 per 100,000 of population as compared with a rate of 5.0 among the native white population of native parentage.

The relative prevalence of general paralysis among the various European races was shown by another chart.

A comparison of discharges and deaths of general paralysis cases, by sex, in New York State and in the United States was shown by two charts. It was demonstrated that the improvement rate is much higher among female cases than among male cases both in New York State and in the United States as a whole, and that the death rate among male cases was much higher than among female, the rates per 1,000 under treatment in the United States in 1922 among males being 304.0, and among females, 261.4. In New York in 1925 the rates were 307.5 and 195.0, respectively.

A chart setting forth the annual economic loss due to syphilitic mental disease in New York State in 1925 estimated the maintenance cost of resident patients in institutions as \$773,343, the loss of earnings of male patients as \$4,438,381, and the loss of earnings of female patients as \$247,203, making a total economic loss for the year of \$5,485,927.

The data on which these charts were based were derived from the Annual Statistical Review of the New York State Hospital Commission and the advance proof sheets of the report of the Federal Census for institutions for mental disease taken January 1, 1923.

THE TREATMENT OF THE ATAXIA OF TABES

By MORRIS CROSSMAN, M D

MOUNT SINAI HOSPITAL

ATAXIA in tabes is one of the most annoying symptoms of the disease, associated with pain, it becomes the bane of the tabetic existence. These two symptoms are chiefly responsible for the mental state usually present in these patients. This mental state, when analyzed, consists mainly of various fears, fear of darkness, fear of crowds, crossing streets, impending disability, and a host of others. The effect of the numerous symptoms upon the mental state varies with the nature of their intensity. Just as the symptoms react on the mental state, so the mental state reacts on the symptoms. In

favorable mental states, pain, ataxia, and other symptoms are diminished, and in unfavorable mental states they are usually exaggerated. On this interdependence of the mental state and the tabetic symptoms rests the basis for the psychological treatment of these symptoms.

This history of tabes abounds with diverse forms of treatment which has produced beneficial results in curing the ataxia. The basis for this improvement can only be a psychological one. Of the many forms of treatment of this symptom, the application of graded forms of exercises is the most logical one. Frenkel in 1897

nine seconds There was a distinct absence of inward pastpointing after turning both to the right and to the left. Caloric tests showed no reactions whatsoever after five minutes douching of each ear Here, of course, is the paradox reaction so often found in hereditary luetic labyrinthitis The diagnosis made was the above, and in addition neurosyphilis was strongly suspected because of the inability to pastpoint inward Spinal fluid examination showed the Wassermann to be three plus, colloidal gold curve 5555431000, albumin and globulin present, sugar normal

Case 3—Woman, age 25 years, had been complaining of a tinnitus and a loss in hearing for ten years She was married and had had three miscarriages She had a large defect in the hard palate due to a healed luetic lesion Her blood Wassermann was two plus Examination of her hearing showed findings characteristic of a bilateral nerve deafness Labyrinthine tests showed shortened after nystagmus, $\frac{1}{2}$ of normal in both directions, shortened vertigo and normal pastpointing The caloric reactions were normal except for the increase in time required to produce a reaction, 1 minute, 20 seconds The diagnosis of luetic deafness of the nerve type was made, neurosyphilis was ruled out because of the normal pastpointing A spinal fluid examination showed a negative Wassermann, normal colloidal gold curve (ten zeros) and no cells

Case 4—Man, age 42 years, previously in good health, the father of two healthy children suddenly noted on coming out of the subway that he could not hear in the left ear He also felt slightly unsteady and had a sensation of falling to the left This attack persisted only for a few hours The deafness, however, continued Examination of the hearing showed total deafness in the left ear and a diminution in bone conduction in the right ear Examination of the vestibular apparatus showed complete absence of all reactions following douching of the left ear and a $\frac{3}{4}$ loss in the duration of the nystagmus after turning to the right, but only a little more than $\frac{1}{4}$ after turning to the left The blood Wassermann was negative The pastpointing reactions, however, showed a distinct inability to pastpoint inward after rotation A diagnosis of neurosyphilis was made Spinal fluid examination showed a four plus Wassermann, colloidal gold curve 5554433100 160 cells to the cmm, increased globulin normal sugar This patient did not remember ever having had any primary or secondary luetic lesions His children and wife were serologically negative

Case 5—Man, age 42 years, consulted Dr S J Kopetzky for a gradual loss in hearing for 16 years Married six years He has no children He had a chancre twenty years ago Functional examination of his hearing showed a nerve deafness as evidenced by his responses to

the tuning forks and to the audiometer Examination of his labyrinth by rotation and by caloric testing gave normal nystagmus, vertigo and pastpointing His blood Wassermann was four plus A diagnosis of luetic nerve deafness was made In view of the normal pastpointing, neurosyphilis was ruled out Spinal examination showed a negative Wassermann, normal colloidal gold curve (ten zeros), no cells, no globulin

In the third group of cases, the chief complaint referable to the ears was a tinnitus These patients had no loss in hearing for air conduction as evidenced either by conversation or by the hearing tests The bone conduction in all, however, was diminished The labyrinth tests showed all reactions to be normal except for the inability to pastpoint inward following stimulation

Case 6—Man, age 31, had a chancre in 1923 He received intensive antiluetic treatment so that at no time after the sixth week of his illness was his blood Wassermann positive Six months after the initial lesion he began to complain of a slight noise in the left ear Neurological examination was negative Examination of the hearing showed a bilateral diminution in bone conduction but no disturbance in air conduction for both high and low tones Functional examination of the labyrinth gave normal nystagmus and vertigo but an inability to pastpoint inward with both hands I wrote the physician who referred the case telling him that I believed the man to be suffering from some form of syphilis of the central nervous system and advised a diagnostic lumbar puncture The spinal fluid showed a four plus Wassermann, 200 cells to the cmm, 90 per cent lymphocytes, colloidal gold curve 555532000, two plus albumin The patient was again treated for one year and re-examination by me at the end of that period showed a normal bone conduction in the right ear and an increase toward normal in the left ear The pointing following caloric stimulation was normal with both hands Following rotation, however, the patient was still unable to pastpoint inward with the left hand on turning to the left This was an improvement over the previous examination On re-examining the spinal fluid, the Wassermann was found to be two plus, the colloidal gold curve normal, the cells reduced to one per cmm, a faint trace of globulin and albumin

Case 7—A man, age 39 years, complained of a slight buzzing noise in his right ear for one week He had no disturbance in hearing He never had, to his knowledge, any venereal disease Functional examination of his hearing revealed normal air conduction for the forks and a slight diminution in bone conduction in both ears Labyrinthine tests revealed normal nystagmus and vertigo, but an inability to pastpoint inward with both hands following rotary stimu-

conduction in both ears. The air conduction for both high and low tones was normal. They complained of no disturbance in hearing. On functional examination of the vestibular apparatus eighteen of the cases showed an abnormal pastpointing reaction following both rotary and caloric stimulation. This in each instance consisted of an inability to pastpoint inward. When the patient was turned to the right, the right hand pointed normally to the right after rotation had been stopped, but the left hand either touched or pointed to the left. Similarly, on turning to the left, the left hand pointed normally to the left, but the right hand either touched or pointed to the right. All other reactions were normal as to character and duration. The nystagmus and vertigo were found normal. In the two cases wherein the pastpointing was normal following stimulation, the diagnosis was *tabes dorsalis*.

All of the twenty cases showed findings in the spinal fluid characteristic of some form of neurosyphilis. In all the spinal fluid Wassermann was positive and the colloidal gold curve of the tabetic, parietic or combined type. Four of the cases, three tabo-parietics and one parietic, were examined after an interval of four months' intensive therapy. In each of the cases the pastpointing reaction was unaltered as to the inability to point inward. The spinal fluid in each case likewise showed no improvement in the luetic reactions. I have not examined any case in this group where the spinal fluid showed a change in the Wassermann reaction or in the colloidal gold curve, but I feel certain that the finding of an inability to pastpoint inward following stimulation will become altered toward the normal as a change for the better is noted. One such case is reported in the other group.

A report of one case in this group will suffice to show what was found in the other seventeen cases.

Case 1—Man, 43 years, married. He had gonorrhea 15 years ago. He does not remember ever having had any luetic lesion. He complained of headaches due to a fall four years previously. His one child is a congenital luetic defective. His blood Wassermann was negative. His spinal fluid Wassermann was four plus, colloidal gold curve 5555432100, 100 cells per cmm, all lymphocytes. Functional examination of the hearing showed a diminution in bone conduction for both ears and a normal air conduction.

	Right	Left	Normal
C 128 air	46	44	45
bone	14	14	20
C 2048 air	37	35	35
C 64	Heard	Heard	Heard

Nystagmus and vertigo following rotary and caloric stimulation were normal in every respect.

The patient was unable to pastpoint inward following stimulation.

Turning	To Right	To Left
Nystagmus	Horizontal, 23 sec. to left.	Horizontal, 24 sec. to right.
Vertigo	.20 sec. to left.	19 sec. to right.
Pastpointing	Right hand to right. Left hand off to left.	Left hand to left. Right hand touches
Caloric 68°	Right Ear	Left Ear
Nystagmus	After 35 sec. rotary to left.	After 33 sec. rotary to right.
Vertigo	.Present.	.Present.
Pastpointing	Right hand to right. Left hand touches	Left hand to left. Right hand touches.
Head Back		
Nystagmus	Changes to horizontal	Changes to horizontal
Pastpointing	Right hand to right. Left hand to left.	Left hand to left. Right hand touches.

This patient was examined again four months later and the same findings were noted on spinal fluid and functional examination of the ears.

In the second group are included all types of deafness that may be produced by syphilis—end-organ, nuclear and nerve trunk lesions, both hereditary and acquired. In the hereditary *luetica*, the greatest number presenting aural lesions show reactions to the labyrinth tests characteristic of an end-organ lesion. The nystagmus and vertigo are either shortened or absent. The pastpointing is either normal or absent depending upon the presence or absence of vertigo. Where the pastpointing is abnormal, and shows the inability of the patient to pastpoint inward following stimulation to the labyrinth, I have found that syphilis of the central nervous system exists in conjunction with the luetic labyrinthitis. Where the pastpointing was normal, the spinal fluid examination likewise showed normal findings.

In the acquired type of labyrinthine syphilis, the finding of an inability to pastpoint inward following stimulation, also speaks for the presence of neurosyphilis. In the cases examined, this reaction was present in all who showed positive spinal fluid findings and was negative in all who showed negative spinal fluid findings, despite the presence or absence of a positive blood Wassermann.

Case 2—A girl, age 13 years, noticed a gradual loss in hearing for the past two years. She had a bilateral interstitial keratitis one year ago. There was no tinnitus, vertigo or equilibratory disturbance at any time. Her blood Wassermann was four plus two years ago, at the time of my examination it was two plus. She had had antiluetic treatment during the entire period. Her father had died of a paralytic stroke due to syphilis.

Functional examination of the hearing both by the forks and by the audiometer showed a distinct nerve deafness in both ears, worse in the left. On rotation, the nystagmus to the right and to the left lasted five seconds and the vertigo

of mercury is tolerated is that the palmitin is very slowly absorbed, taking 3 to 5 days, thus giving an opportunity for simultaneous absorption and elimination

The neosalvarsan is given in doses of 0.1 gr (2 cc of the solution) to a child under two years of age, and is increased in proportion according to age. If more than 2 cc of the solution is to be given, the dose is to be divided into equal parts and given into both buttocks

REACTIONS

Reactions are very rare and when they do occur they are very mild. There have not been observed any reactions from the mercurial injections. Following the neosalvarsan there is rarely an infiltration of the buttock (about 1 in 500 injections). Occasionally transient vomiting occurs several hours after treatment. Herthimer reactions, dermatitis exfoliativa or jaundice have never been observed. Pain at the site of injection is slight. The children appear happy and playful a short time after treatment and remain so during the entire weekly interval.

LENGTH OF TIME TREATMENT IS CONTINUED

Irrespective of serologic report each luetic child is given at least three or four courses of the above described treatment. After four courses of treatment have been given and the serologic findings both of the blood and spinal fluid are negative and there are no clinical manifestations

of the disease, treatment is discontinued and the patient is ordered to return for observation and serological tests at intervals of 3-6 months. If on the other hand there are persistent positive fluid or clinical manifestations of lues, the treatment is repeated with short rest intervals.

RESULTS OBTAINED

The majority of children so treated show a rapid improvement in general health and nutrition simultaneously with the clearing up of luetic lesions of skin, mucous membranes, bones, etc. The best clinical and serological results are obtained in children in whom treatment is begun soon after birth. The older the child is when treatment is first instituted, the more resistant it seems to be to spirocheticides.

Out of a small series of 50 cases at the Out-patient department of the Mt Sinai Hospital admitted during the last 4-5 years, 36 remain under observation and of this number 15, or 42 per cent, have remained clinically well and serologically negative for one year or longer. The remaining 21 cases are under active treatment and are progressing favorably.

CONCLUSION

The above method offers a safe, easy, and simple means of treating congenital lues by the general practitioner as well as the syphilologist, with the most gratifying results.

THE THERAPY OF SYPHILIS

By LOUIS CHARGIN, MD and ABRAHAM STONE, MD

DEPARTMENT OF HEALTH NEW YORK CITY

THE development of modern diagnostic methods, the introduction of the newer antisyphilitic remedies, and our increasing knowledge of the pathology of syphilis have led to a change in our conception of the treatment of disease. Particularly does this apply to the treatment of early syphilis. Formerly, a positive diagnosis of the disease frequently could not be established until the appearance of secondary manifestations, and, as a result, the treatment was often unduly delayed. The newer diagnostic methods make it possible to detect syphilis at its inception, and thus to begin treatment very early in the disease. Treatment during this period, especially before the appearance of a positive Wassermann, offers the best chances for a cure.

There is a general unanimity of opinion at the present time in regard to the standards of antisyphilitic therapy, but certain details of treatment are still a matter of controversy. Numerous plans, varying as to the kind and number of injections, dosage, frequency of treatments, length of rest periods between treatments, etc., have been suggested by various observers. Each

plan has its advocates, but it is perhaps true that at present no one plan can be considered as the ideal, and no one plan is applicable to the disease in all its stages.

The drugs employed in the treatment of syphilis are arsenic, mercury, bismuth and iodides. Of the arsenicals, arsphenamine, neo-arsphenamine, sulph-arsphenamine, silver-arsphenamine, sodium-arsphenamine and other arsphenamines. In the case of mercury, as well as bismuth, an ever increasing number of preparations are being recommended. Each of these drugs has its distinctive value in the therapy of syphilis, and the use of one or the other depends upon the stage of the infection, the character of the symptoms, etc.

The general practitioner has but little opportunity to test for himself the various therapeutic measures advocated. He must necessarily rely upon the opinions of those who have more specialized knowledge, of those who have had the opportunity to evaluate the drugs and methods of treatment from a practical standpoint.

The exhibit on the "Therapy of Syphilis" was

lation A tentative diagnosis of neurosyphilis was made in spite of the fact that there were no clinical stigmata The blood Wasserman examined at two different laboratories was reported negative Spinal fluid examination showed no cells, no globulin, colloidal gold curve normal (ten zeros) but the Wassermann reaction, as reported by Dr Losee, was positive down to the smallest titration I again rotated the patient following lumbar puncture and noted a distinct alteration in the pointing reaction The past-pointing after turning to the left was normal with both hands After turning to the right, however, the inability to pastpoint inward with the left hand persisted

SUMMARY

I do not attempt to explain the reason for the constancy of this reaction in the cases of neurosyphilis that I have examined It possibly may be due to some pressure in the posterior cranial fossa This seemed to be evident in the last case reported wherein the reaction was altered toward normal after the relief of pressure by lum-

bar puncture I am simply reporting my findings, and have arrived at these conclusions

1 The labyrinth tests and the examination of the hearing furnish us with a valuable aid in determining the presence of neurosyphilis in its earliest stages

2 The finding of an inability to pastpoint inward should lead one to suspect neurosyphilis While it is possible that other conditions may produce this faulty reaction, its presence in the majority of cases of neurosyphilis examined by me causes me to recommend a careful search for this disease where the inability to pastpoint inward exists

3 If this inability to pastpoint inward is associated with a diminution in bone conduction, the diagnosis of neurosyphilis becomes a probability

4 The beneficial effect of treatment on neurosyphilis is demonstrable by a return of the past-pointing reaction toward normal

5 I believe that the use of the labyrinth tests should be more extensive in conjunction with the treatment of syphilis so as to determine early invasion of the central nervous system

TREATMENT OF CONGENITAL LUES IN INFANTS AND YOUNG CHILDREN

By HARRY SHERWOOD, M D,

VANDERBILT CLINIC AND MOUNT SINAI HOSPITAL NEW YORK

THE treatment of lues in infants and young children presents more difficulties than the treatment of the same disease in the adult Intravenous medication is not practical and even in the best hands, not always possible Intramuscular medication has not been very popular until recent years The sole method of treatment in these cases has been that by mercurial inunctions This latter method, of course, was insufficient in the majority of cases and at best depended on the thoroughness and regularity with which it was carried out

In 1921 Doctors Fordyce and Rosen inaugurated a new method of treatment of congenital lues at the Vanderbilt Clinic and the Out-patient Department of Mt Sinai Hospital, namely, by means of intramuscular injections of alternate doses of a soluble mercurial salt and neosalvarsan at weekly intervals The injections are given by means of a special needle, known as the "Rosen needle" This latter has as its characteristic feature two slightly curved lateral flanges attached to the hub which conform to the curve of the buttock and enable the physician to hold the needle in place while injecting medication The injections are made in the upper inner quadrant of the buttock, and are followed by massage After injecting without withdrawing the needle, the syringe is disconnected, a small quantity of air is drawn into it, then injected

through needle in order to expel the small quantity of mercury remaining in the bore of the needle

COURSE OF TREATMENT

A course of the above combined treatment consists of 4 mercurial injections followed by 6-8 intramuscular neosalvarsan injections and then followed by 4 more mercurial injections, all at weekly intervals After the completion of the course of treatment, a month's rest is given the patient At the end of this time the Wassermann test is done and according to the outcome of the test, the course of treatment is either repeated or a further rest period is given

PREPARATIONS USED

Mercury is used in the form of "Bichloridol" This consists of bichlorid of mercury incorporated in palmitin and is placed in soft collapsibles Before using, the contents of the collapsible tube are expressed into a sterile syringe and heated in hot water in order to melt the palmitin

The neosalvarsan is used in 1/20 solution (2 cc of sterile distilled water to each 0.1 gm of neosalvarsan) Bichloridol is given in doses of 1/20 gr of bichloride of mercury to a child under two years of age, and 1/5 gr of bichloride of mercury to a child over two years age The reason why such a large dose of bichloride

a platinum wire, a loopful is transferred to a slide and topped with a cover glass. Next, and of importance is the proper use of the oil of cedar, a drop of which is placed on the dark-field condenser, a drop on the under surface of the slide, and a drop on the cover glass. We then have a solid column of oil and glass from condenser to lens. Of the various sources of light, the best is the arc lamp. The search for the organism may now be instituted.

A word of caution is fitting. A positive dark-field is conclusive—a negative one is by no means final. Many and repeated attempts on the same and successive days should be made before a genital lesion—suspicious or otherwise—is pronounced negative. Puncture of an enlarged gland that drains the site of infection, and examination of some of the serum obtained may yield the spirochaete. When it is difficult to obtain serum, the injection and withdrawal of one or two drops of saline may give positive results.

The spirochaeta pallida is a flagellated protozoon with no undulating membrane. Microscopically, it is unlike most other spirochaetes. It has three distinct motions—a rotary one, a sharp linking movement, and longer waving one. The spirals are geometrically regular and sharply and deeply cut, numbering 6 to 26 turns. The organism is 6 to 15 microns long, about a quarter of a micron in diameter. It is important to note that the spiral form is maintained at rest as well

as when in motion. It must be distinguished from the following organisms:

S. Vincenti, which is a delicate organism as long as the *S. pallida* but with very few curves. *S. Vincenti* is always seen in symbiosis with a fusiform bacillus. It stains readily.

S. refringens, which is thicker and band-like, less regular and with more flattened curves possessing under the dark-field a yellowish tint.

S. microdentium closely resembles *S. pallida* although usually somewhat shorter. Its usual habitat is the mouth, and is of importance therefore only when the lesion is present in or near the mouth. Of all the spirochaetes, this one is most apt to be confused with spirochaeta pallida. Culturally it may be differentiated.

S. buccalis is 12 to 20 microns long but has only 4 or 5 large shallow irregular curves. It also is an inhabitant of the mouth.

To sum up

The earliest diagnosis of syphilis may be made by the detection of the spirochaete in the primary lesion.

The dark-field is the easiest and most accurate method for that purpose.

Waiting for a positive Wassermann or for the appearance of a secondary rash is inexcusable in the presence of a primary lesion.

It was to bring out these facts that this part of the symposium was staged.

THE NEW YORK STATE HEALTH DEPARTMENT EXHIBIT

By ALBERT PFEIFFER, MD

Director Division of Social Hygiene AA Surgeon USPHS

THE novelty of the exhibit and the feature which attracted the most attention were the films showing syphilitic lesions and lesions simulating syphilis. These hundreds of photographs of typical and of unusual cases were well worth serious consideration. These films were provided by the U. S. Public Health Service co-operating with the State Department of Health. A general idea of the extensiveness and of the value of these films is indicated by their titles:

Treponema Pallidum	Noguchi
Miscellaneous Lesions	Paris Museum
Lesions of Syphilis	Lautman
Early Syphilis	Mackee
Late Syphilis	Mackee
Primary Syphilis	Mackee
Congenital Syphilis	Mackee
Chancres	Paroungian
Lesions Simulating Syphilis	Paroungian
Lesions of Syphilis	Paroungian
Lesions of Syphilis	Engman and Mook

Possibly the instructive value of this display was not altogether responsible for the attention

it attracted. The battery of eleven day-light projecting machines in line was impressive in itself. Ten of these delmeascopes were provided with films of twenty to one hundred photographs and were operated by the visiting physicians. The eleventh one was automatic and ran continuously. The success of this unusual method for displaying effectively hundreds of pictures warrants its use more generally.

MOULAGES

One of the greatest disadvantages in clinical teaching is the difficulty in getting actual cases showing typical lesions at the proper time. Usually this is cared for to a large degree by adapting the didactic work to the clinical material at hand. This is comparatively simple and successful in medical schools but for the occasional demonstration or brief post-graduate course this method is impracticable. When clinical material is not available, life-like reproductions in wax are useful. If these models are accurately and expertly made they are very satisfactory and they are available at any and at all

prepared with the object of epitomizing for the general practitioner the present status of anti-syphilitic therapy. It was aimed to make the exhibit practical and concrete, so that the visiting physician might derive from it some definite and useful information. At the same time, however, the therapeutical basis for the use of the remedies and methods suggested were presented and discussed.

The exhibit included a series of charts which gave a resumé of the various agents employed in the treatment of syphilis and of the main plans of treatment in use. Some of the plans detailed were:

The Chronic Intermittent Plan—This plan, introduced by Neisser, has been modified later by various syphilographers. It consists of regular courses of arsphenamine and mercury, or arsphenamine and bismuth injections, alternating with periods of rest during which no treatment is given. This plan is the one most widely accepted and used at the present time. A course usually consists of 8-10 arsphenamine injections, given 5-7 days apart and 12-15 mercury or bismuth injections, given once a week or oftener. Each course is followed by a period of rest, usually of about 4-8 weeks. Further courses, alternating with rest periods, are then given, depending upon the clinical and serological findings.

The Very Intensive Plan—This method was suggested by Scholtz, and modified by Pollitzer. It aims to saturate the patient with the arsenical at the beginning of each course of treatment, so as to affect a rapid sterilization. For this purpose the arsphenamine injections are administered in fairly large doses and at very short intervals (daily, for the first three days) at the beginning of the course. This is followed by a series of mercury injections, and the course is terminated by another series of arsphenamine injections.

The Mixed-Injection Methods—This plan of

treatment was introduced by Linser. It consists of injecting a mixture of neo-arsphenamine and bichloride (or other similar mixture) instead of administering these drugs separately. These treatments are given in courses of 8-10 injections, alternating with periods of rest.

The Continuous-Treatment Plan—This plan, suggested by Almquist, differs from the others in that the treatments are given continuously, without any rest periods. The drugs employed are administered in alternating courses. First, a course of arsphenamine is given, 6-8 injections, this is followed by 6-8 weekly injections of mercury, then again a course of arsphenamine, followed by a series of mercury injections, etc. These series of treatments are continued, if indicated, for as long as a year.

In addition to the charts, a practical demonstration was given of drugs employed, the mode of preparation, and manner of use. The various arsphenamines were mixed and prepared for administration. The glassware, syringes, needles and other apparatus used for this purpose were exhibited. A large number of preparations of arsenic, mercury and bismuth were shown, and the merits and demerits of the various products discussed.

Another feature of the exhibit was a series of slides, emphasizing important points and axioms in anti-syphilitic therapy, which were thrown upon a screen by a stereomotograph. The slides called attention to the need for beginning the treatment early, for continuing it over a sufficiently long period of time, to the need for care in the technique of preparation and administration of the drugs, to the need for careful and repeated examinations of the patient, the importance of detecting early the by-effects of treatment, and to other salient factors in the care of the syphilitic.

The charts, slides and demonstrations were augmented by personal discussions, which served to clarify the various points raised.

THE SPIROCHAETE DEMONSTRATION

By DR ADOLPH JACOBY, DR MAXIMILIAN NEMSER, DR WALTER SECKEL

DEPARTMENT OF HEALTH NEW YORK CITY

TO obtain the best therapeutic results in the treatment of syphilis, the diagnosis should be made as early as possible after infection has taken place. This is best done by examining the suspected lesion for the spirochaeta pallida. The method of choice for such examination is the dark-field.

In the dark-field method the organism is shown in the living state. The method, though exact and somewhat painstaking, is easily mastered. It was with the object of demonstrating this technique that this particular part of the symposium was staged. In examining for the spiro-

chaeta pallida by the dark-field method, a matter of prime importance is the making of the preparation. The lesion must be free from drug or medicament—free for a period of at least 24 hours preceding the examination. It must be carefully wiped, all debris and pus removed and then sufficiently irritated at the margin either by being wiped with gauze or otherwise, to produce an exudation of serum. The exudate at the edges is more apt to show the organism. It is well to wait until clear or almost clear serum covers the irritated surface, sufficiently in quantity to make a suitable preparation. By means of

a platinum wire, a loopful is transferred to a slide and topped with a cover glass. Next, and of importance is the proper use of the oil of cedar, a drop of which is placed on the dark-field condenser, a drop on the under surface of the slide, and a drop on the cover glass. We then have a solid column of oil and glass from condenser to lens. Of the various sources of light, the best is the arc lamp. The search for the organism may now be instituted.

A word of caution is fitting. A positive dark-field is conclusive—a negative one is by no means final. Many and repeated attempts on the same and successive days should be made before a genital lesion—suspicious or otherwise—is pronounced negative. Puncture of an enlarged gland that drains the site of infection, and examination of some of the serum obtained may yield the spirochaete. When it is difficult to obtain serum, the injection and withdrawal of one or two drops of saline may give positive results.

The spirochaeta pallida is a flagellated protozoon with no undulating membrane. Microscopically, it is unlike most other spirochaetes. It has three distinct motions—a rotary one, a sharp kinking movement, and longer waving one. The spirals are geometrically regular and sharply and deeply cut, numbering 6 to 26 turns. The organism is 6 to 15 microns long, about a quarter of a micron in diameter. It is important to note that the spiral form is maintained at rest as well

as when in motion. It must be distinguished from the following organisms.

S. Vincenti, which is a delicate organism as long as the *S. pallida* but with very few curves. *S. Vincenti* is always seen in symbiosis with a fusiform bacillus. It stains readily.

S. refringens, which is thicker and band-like, less regular and with more flattened curves possessing under the dark-field a yellowish tint.

S. microdentium closely resembles *S. pallida* although usually somewhat shorter. Its usual habitat is the mouth, and is of importance therefore only when the lesion is present in or near the mouth. Of all the spirochaetes, this one is most apt to be confused with spirochaeta pallida. Culturally it may be differentiated.

S. buccalis is 12 to 20 microns long, but has only 4 or 5 large shallow irregular curves. It also is an inhabitant of the mouth.

To sum up

The earliest diagnosis of syphilis may be made by the detection of the spirochaete in the primary lesion.

The dark-field is the easiest and most accurate method for that purpose.

Waiting for a positive Wassermann or for the appearance of a secondary rash is inexcusable in the presence of a primary lesion.

It was to bring out these facts that this part of the symposium was staged.

THE NEW YORK STATE HEALTH DEPARTMENT EXHIBIT

By ALBERT PFEIFFER, M D

Director, Division of Social Hygiene, A A Surgeon, USPHS

THE novelty of the exhibit and the feature which attracted the most attention were the films showing syphilitic lesions and lesions simulating syphilis. These hundreds of photographs of typical and of unusual cases were well worth serious consideration. These films were provided by the U S Public Health Service co-operating with the State Department of Health. A general idea of the extensiveness and of the value of these films is indicated by their titles:

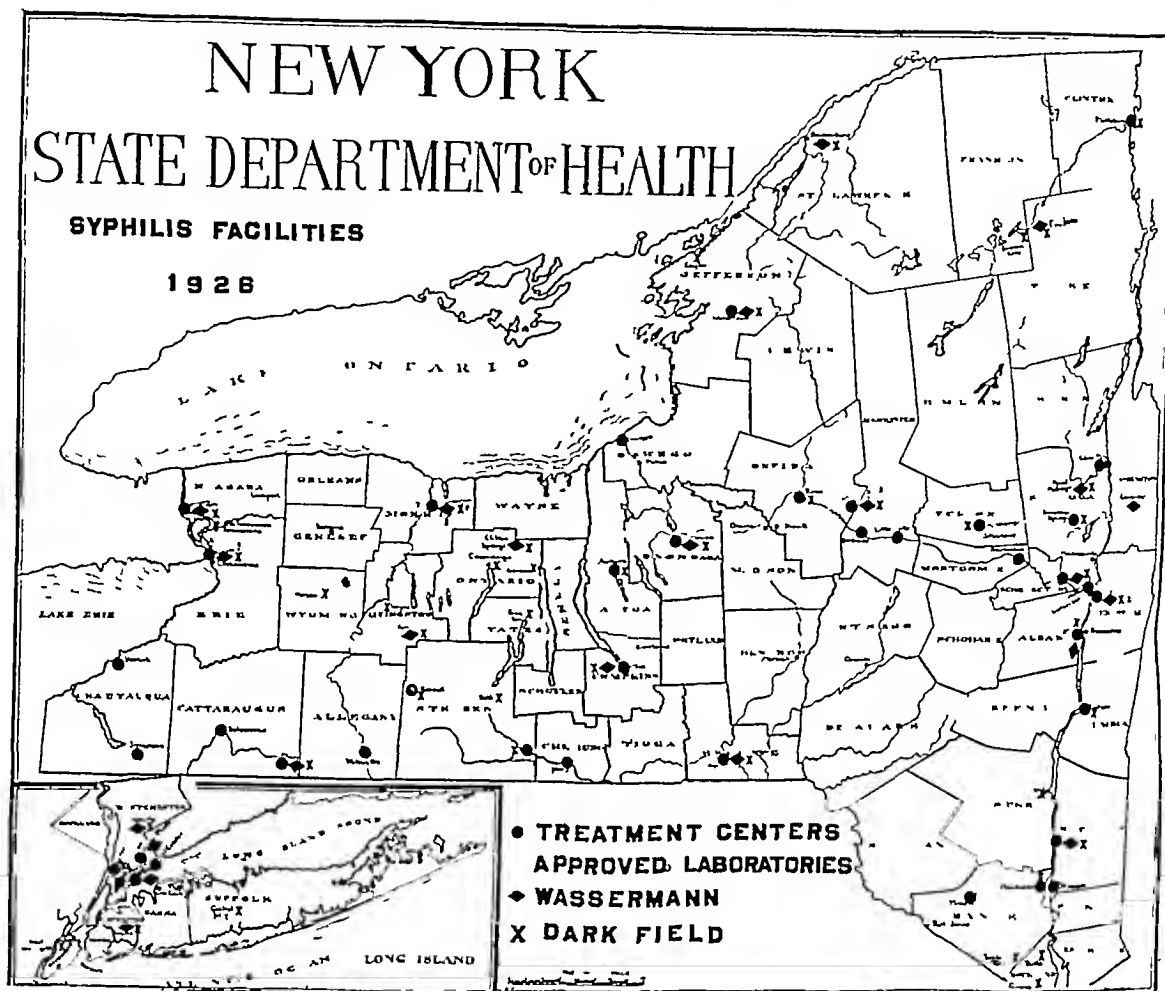

Treponema Pallidum	Noguchi
Miscellaneous Lesions	Paris Museum
Lesions of Syphilis	Lautman
Early Syphilis	Mackee
Late Syphilis	Mackee
Primary Syphilis	Mackee
Congenital Syphilis	Mackee
Chancres	Parounagian
Lesions Simulating Syphilis	Parounagian
Lesions of Syphilis	Parounagian
Lesions of Syphilis	Engman and Mook

Possibly the instructive value of this display was not altogether responsible for the attention

it attracted. The battery of eleven day-light projecting machines in line was impressive in itself. Ten of these delineascopes were provided with films of twenty to one hundred photographs and were operated by the visiting physicians. The eleventh one was automatic and ran continuously. The success of this unusual method for displaying effectively hundreds of pictures warrants its use more generally.

MOULAGES

One of the greatest disadvantages in clinical teaching is the difficulty in getting actual cases showing typical lesions at the proper time. Usually this is cared for to a large degree by adapting the didactic work to the clinical material at hand. This is comparatively simple and successful in medical schools but for the occasional demonstration or brief post-graduate course this method is impracticable. When clinic material is not available, life-like reproductions in wax are useful. If these models are accurately and expertly made they are very satisfactory and they are available at any and at all

times The Division exhibited several hundred excellent wax models. These moulages impressed physicians again with the truth of the old statement that syphilis manifests itself in manifold ways and hence has earned for itself the name of the "great imitator," and that since syphilis simulates almost every disease it is imperative that it shall be eliminated in every diagnosis.

The models assist materially in classifying differential diagnoses.

The ever present large and interested attendance gathered about the table of wax models demonstrated clearly the popularity of this exhibit.

CHARTS

One of the most effective ways to interpret figures and to impress the relative change in facts over a period of time is to visualize the data by means of charts. Statistics then take on form and have new significance.

The following descriptions give a general idea of the type of statistical charts displayed.

1 Graphs showing the slow, constant and

healthy growth year by year in the number of physicians searching for syphilis, indicating that there are many, a majority which is getting larger, practising physicians who discover or eliminate syphilis in their diagnoses.

2 A map of the State showing the location of laboratories approved for Wassermann tests or dark field examinations and also the location of the free treatment centers where physicians can refer their indigent cases or have part of the treatment and tests carried out. These clinics also afford the practising physician an opportunity for post-graduate study.

3 A graphic presentation of the continuous and rapidly increasing use of approved laboratories by physicians for diagnostic and prognostic purposes.

4 A diagram showing the cases of syphilis and gonorrhea brought under treatment for the first time each year which makes clear that the number of infected persons seeking treatment for the first time is not tending to decrease but rather remains practically constant.

The statistical data would seem to indicate that syphilis offers a very fertile field to the prac-

tising physicians, especially those who wish to give service both to the individual and to society or those interested in study and research. Perhaps there is no disease which draws so extensively on knowledge, skill, judgment and resourcefulness of a physician as the diagnosis and treatment of syphilis. Yet it responds most satisfactorily under approved intensive modern treatment when administered early in the disease.

LITERATURE

Whereas visual education has come to be recognized as of enormous value and the display of hundreds of clinical cases and photographic and wax reproductions is of infinite value, for the purpose of serious study it is necessary or at least desirable to have the detailed information carefully and clearly stated in permanent form for ready reference. For this nothing can take the place of the printed word and so in order to supplement the other more ephemeral exhibits there was an abundance of practical literature for distribution.

Transactions of the Conference of Venereal Disease Control. Officers of the State Health Departments and USPHS, 1924. Bulletin No. 77.

Preparation and Administration of Arsphenamine and Neoarsphenamine, USPHS Bulletin No. 774.

Sulpharsphenamine in the Treatment of Syphilis. Albert Pfeiffer, M.R.C.S., L.R.C.P.
Fundamentals of Syphilis. Brunet and Pfeiffer.

Compilations of the Laws and Regulations Relating to Gonorrhea, Syphilis and Chancroid.

Syphilis, Gonorrhea and Chancroid. Pamphlets supplied to physicians for their venereally infected patients.

Samples of literature for lay people.

Some physicians and dentists are keeping a supply of the various pamphlets or post cards listing such pamphlets issued by the State Health Department on the tables in their waiting room. In this way the public is put in touch with the

available material and the physicians report that the patients are more willing to continue their treatment over the entire period necessary in syphilis after they have read the literature and are assured from an authoritative source of the need of such supervision.

SUMMARY

Several rather definite objectives were kept in view in preparing the exhibit. The casual comments and reports seem to indicate that these ideas carried across successfully in many instances.

1 To create a determination in every physician to eliminate syphilis in each diagnosis.

2 To stimulate the physician to utilize every modern diagnostic measure, the dark field, blood and spinal fluid tests, etc., in examinations.

3 To impress the physician with the need for intensive treatment. Modern diagnostic and treatment methods are sufficiently well developed to eliminate syphilis, if intensively and extensively utilized. Unquestionably there will be improvements in the methods of diagnosis, laboratory tests, therapeutic agents and the methods of treatment, but the knowledge available today is adequate to cope successfully with syphilis without waiting for the further advancement of scientific methods. Sulpharsphenamine makes it practical for any general practitioner to treat syphilis successfully, at least in the early stages when not complicated by cardio-vascular or neuro-syphilitic involvement.

4 To encourage physicians to learn early diagnosis. Lesions should be definitely identified early in order to avoid subsequent complications of the heart, aorta and nervous system. It is not necessary nor desirable to wait until the Wassermann becomes positive. Physicians should learn to diagnose syphilis early by the dark field examination and to administer intensive treatment. The common presence of aneurysms and neuro-syphilis can be regarded as proof that many patients are either not diagnosed as specific cases or that the treatment has been incomplete.

SYPHILIS IN THE NEGRO

By HOWARD FOX, M.D.

NEW YORK UNIVERSITY NEW YORK CITY

The prevalence of syphilis in the American negro is undoubtedly greater than in the white race. It is, however, incorrect and unjust to claim as some do without proof that half or more of the negroes of this country are syphilitic. From statistics that I formerly compiled from the Central Dispensary in Washington, it was found that the disease occurred approximately one and one-half times as often in negroes as in whites. The figures showed that

in 15,000 white (in round numbers) there were 621 cases (4.1%) of syphilis, while in 32,000 negroes, approximately 1,900 (5.9%) were affected with syphilis. Rudolph Matas found a proportion of fifty-one cases of syphilis in negroes as opposed to twenty-eight in whites in one thousand patients.

The age at which infection occurs is apparently earlier in the American negro than in the white race, due to lower standards of mo-

rality, the prevalence of the disease, and the earlier age of maturity. Zimmermann found that a much greater number of infections occurred before the twentieth year in negroes than in whites.

The severity of the disease is in general milder in the negro race and it appears to be more amenable to treatment. It is most probable that the proportion of late manifestations (nervous and visceral) would be lessened if the negro could appreciate more fully the seriousness of the infection and the importance of continuing treatment after the early symptoms had disappeared.

The manifestations of syphilis show many variations in frequency and severity in the two races for which numerous causes have been suggested. The initial lesion in the negro is more frequently multiple and less apt to be extragenital than in the white race. At least one syphilitic manifestation may be considered as a racial characteristic. This is the so-called annular syphilide, which occurs as an early (secondary) eruption. It is seen most frequently on the face, less often on the upper portions of the trunk. The lesions are formed by centrifugal extension of papules, mostly of the flat variety, the central portions becoming deeply pigmented and surrounded by elevated borders. Concentric circles and polycyclic figures at times produce a most striking and diagnostic picture.

Among the other early syphilides the macular type is less frequently observed in negroes than in whites, doubtless due in part to the dark color of the skin. Palmar lesions are also less common in this race. Pustular syphilides, on the contrary, are much more common in negroes than in whites. The type composed of small pustules resembling variola is especial-

ly difficult at times to recognize, numerous patients with this variety of eruption having been unnecessarily quarantined until the true nature of the disease was recognized. Condylomata, especially in women, are decidedly more common in negroes than in whites, Hazen even stating that all syphilitic women suffer from this manifestation at some time. The papular types of syphilis also tend at times to be unusually scaly, especially upon the lower extremities, due in part, to the sparing use of soap and water.

Pruritus is said to be more common in cutaneous syphilis of negroes than of whites. While the negro may complain of itching he seldom presents much objective evidence of scratching, the rule holding good for both races that the lesions of syphilis do not itch. Syphilitic adenopathy is more common in the negro race and the same in true of iritis.

The late (tertiary) manifestations of the skin are approximately equal in occurrence and severity in both races. In the negro bone lesions are more frequent than in whites, and syphilitic elephantiasis of the vulva appears to be relatively common. Cardiovascular syphilis is more frequent in the negro than in the white, the proportion being two to one according to Zimmermann. Neurosyphilis is less frequent in the negro, especially tabes and paresis. Cerebrospinal syphilis is probably of equal frequency in the two races.

Leucoplakia, while not a direct manifestation of syphilis, is preceded by syphilitic infection in a sufficiently large number of cases to warrant a relationship between the two diseases. Leucoplakia is generally agreed to be rare in the negro. I found it to be unusually so in the full-blooded negro during my previous long service in the Harlem Hospital.

THE AMERICAN SOCIAL HYGIENE ASSOCIATION

By WALTER M. BRUNET, M.D.
NEW YORK CITY

On Thursday, April 1st, the day devoted to a demonstration of syphilis, the American Social Hygiene Association arranged an exhibit under the direction of Dr. Walter M. Brunet of the Association's Department of Medical Measures.

Stereopticon slides which approached the prevention of the venereal diseases from the public health standpoint were continuously displayed. These slides showed, first, how other contagious diseases have been combated and then the modern program for combating the venereal diseases. A number of wax models presented graphically the various stages in the development of syphilis. These, together

with scientific anatomical charts and samples of recent pamphlets on the venereal diseases emphasized the medical measures aspect of the program.

In order to point out also the educational approach in the control and prevention of the venereal diseases, part of the film "The Gift of Life," as adapted for use in the delinescope, was shown. This machine is easily manipulated and the film may be run through quickly or slowly and turned backward as well as forward by the person studying it. The educational poster exhibits, "Youth and Life" and "Keeping Fit," were on display as well as book and pamphlets dealing with sex education.

DEMONSTRATION OF THE KAHN TEST

By R. L. KAHN, Sc.D

Department of Health Lansing Michigan

THE Kahn test for the serum diagnosis of syphilis is based upon the immunological principle of precipitation. It comprises a routine test with serum for the general laboratory diagnosis of syphilis, a quantitative procedure for determining the relative number of serum reacting substances, particularly in treated cases, and a spinal fluid procedure to be employed in the diagnosis of neurosyphilis.

There are several reasons why the Kahn test has proved a reliable and practicable procedure in the experience of so many workers. Among the more important are the following:

Stability of reagents—Antigen, the one reagent required aside from patient's serum and physiologic salt solution, is easily prepared and standardized and is a stable product. Antigen can be distributed from a central laboratory with no danger of deterioration or change.

Only few minutes required for test—The test does not require incubation. The total time for completing the test from the time blood is drawn from the patient is less than one hour. (Separation of serum from blood clot by centrifugation, 15 minutes, heating of serum at 56° C, 30 minutes, performance of test, 5 minutes.)

Sources of error reduced to minimum—The test is relatively free from sources of error, due to the comparative simplicity of technique and to the fact that no step in the test is removed from the eye of the worker who performs it. This is not true with tests which require incubation.

Dependability—The test is specific for syphilis, judged by clinical findings. It seems to be less influenced than the Wassermann test by pathological conditions other than syphilis. It is also somewhat more sensitive than the Wassermann test in early primary and treated syphilis.

The Kahn test was demonstrated at half hour intervals during the demonstration day, using positive and negative serums furnished by the New York City Department of Health.

The test requires three tubes, each containing a different proportion of serum and diluted antigen, as outlined:

	Tube No		
	1	2	3
Serum	3 1	6 1	12 1
Diluted antigen, cc	0 05	0 025	0 0125
Serum (heated) cc.	0 15	0 15	0 15

Completion of Test—Shake 3 minutes. Add 1 cc saline to Tube 1 and 0.5 cc. to Tubes 2 and 3. Syphilitic sera show precipitates, non-syphilitic sera remain clear.

Interpretation of Results—Results are read on basis of 4+, 3+, 2+, 1+ and ±, depending on distinctness of precipitate. The final result is the average of the findings in the three tubes. Thus if precipitation is complete (4+) in all three tubes, the total reading is 12+ and the final result is 4+. If some tubes show only partial precipitation and the total reading, let us say, is 6+, then the final result is 2+.

SOME QUESTIONS ASKED DURING THE DEMONSTRATION, WITH ANSWERS

1 Is it recommended that the Kahn test be performed by physicians in connection with their private practice?

No. The test should be carried out by trained laboratory workers. There is no reason, however, why physicians who are located in isolated areas removed from laboratories could not learn to perform it. We know of physicians who are performing this test with good results in China and other parts of the world removed from medical centers.

2 Are there any institutions which employ the Kahn test without the Wassermann?

Aside from numerous hospital laboratories, the Michigan Department of Health made the Kahn test official, October, 1925, and the U S Navy, December, 1925. In the former institution alone over 32,000 Kahn tests have already been reported to physicians with satisfactory results.

3 Are Kahn tests with small numbers of serums as dependable as with large numbers?

Yes. One serum may be examined with perfectly dependable results. Of course, the finding should be controlled by at least one known positive and negative serum examined at the same time.

4 Is the Kahn test specific for syphilis in the febrile diseases?

So far as we know, the test is not only specific in the febrile diseases but also in non-febrile pathological conditions of a non-syphilitic character. The occasional non-specific results of the Wassermann test in such conditions are undoubtedly due to changes in the serum which increase the fixation powers of complement. The Kahn does not employ complement and is thus free from non-specific complement fixation or anticomplementary reactions. It should not be assumed, however, that the test is perfect. No biological test can approach the perfection of a physical or chemical test.

5 What is the significance of a four plus

Kahn test in the absence of clinical evidence of syphilis?

Our findings indicate that a four plus Kahn test means syphilis. However, a Kahn test or any laboratory test should be considered only as a single manifestation of syphilis to be interpreted in the light of clinical evidence or a history of infection. The final diagnosis of syphilis and the decision as to treatment of a given case are problems of the clinician.

6 What does the quantitative test actually show in serums from treated cases?

The blood of a patient before treatment may show 400 reacting units, at the end of the first course of treatment 200 units, and at the end of the second and third courses 120 and 40 units, respectively. The routine test in all these examinations would be four plus and give no indication as to the serologic effect of the treatment. Some institutions, such as the U S Naval Medical School, report to physicians the results of the quantitative procedure in the case of all serums giving a four plus reaction. This gives the physician the relative potency of serums before treatment with which to compare results after treatment.

7 What is the procedure when there is insufficient serum for a regular test?

If 0.3 cc of serum is available, a two-tube test is run, employing the lesser amounts of antigen dilution. If only 0.15 cc of serum is available a one-tube test is run, employing the least amount of antigen dilution. In this case, the report to the physicians should state "Negative (or positive) in one tube, insufficient for a complete test which requires three tubes." If only one drop (0.05 cc) of serum is available a one-tube test may be made, employing 0.005 cc of diluted antigen.

8 Does one need to titrate the antigen for the Kahn test, every time the test is performed?

Antigen is titrated or standardized once and is then ready for use without further titration. Miss Kendrick showed in our laboratory that an antigen has the same titre when first prepared as two years later.

EDITORIAL COMMENT

The task of securing descriptions of the exhibits was almost as great as that of assembling the material that was shown. The exhibition was new and novel, and there was no precedent for guidance. When the exhibitors were invited, they asked what they should show and say, and each was given freedom of choice. While there was individuality in the exhibits, yet the result was a harmonious whole.

When the demonstrators were invited to make permanent records of their exhibits, their in-

dividualities of style were even more marked than their exhibits. They felt that while their reputations could endure the strain of a transient demonstration, yet it was quite another matter to set a standard for others to emulate. The descriptions which were handed in followed a great variety of forms, from set papers to vivid outlines in few words. All were of a high order, and the writers merit the praise of the medical profession for presenting the entire subject of syphilis in a graphic form.

PAPERS READ IN THE AFTERNOON SESSION

WHAT PRICE SYPHILIS?

By WILLIAM F SNOW, M D, AND WALTER M BRUNET, M D

The American Social Hygiene Association, 370 Seventh Avenue, New York

THE history of syphilis, like that of other dangerous communicable diseases, is one of gradually discovering the identity, cause, and treatment of the disease. In contrast to many other diseases, however, there have been long gaps between the discoveries. The identity of syphilis dates back at least as far as the discovery of America, but the identity of the spirochete of syphilis was demonstrated scarcely two decades ago after more than one hundred announced discoveries of a casual organism had been disproved. The treatment of syphilis in the modern sense dates back hardly fifteen years. Moreover, it may be said that the diagnosis and treatment are still in an early formative stage. When we add to these the further facts that syphilis is most insidious in its attack, imitative of other diseases, indirect in its methods of maiming and killing its victims, and favored by the complicated relations between the moral and the medical aspects of treatment and eradication, we can understand why organized efforts to combat the disease have been so long delayed.

Theoretically syphilis can be eradicated more readily than most of the other dangerous communicable diseases, but practically eradication can be realized only through full co-operation of the people, the physicians, and the health officers all working intelligently and continuously together. This means an immense cost of time and educational effort. The last ten years have seen great strides toward the development of a practical program for the essential teamwork of these three groups. In a survey of 227 cities in 1913 physicians were found to have little interest in the problem of combating the venereal disease, only 4 cities had free venereal disease clinics, 3 provided hospital care for dangerous cases, 46 provided laboratory diagnostic facilities, and only 7 made any attempt to study prevalence and control of the disease by requiring notification. By contrast, in 1923 practically all of the 100 cities having a population above 70,000 have regulations for notification and show increasing use of reports, 82 per cent have free laboratory diagnostic facilities, 100 per cent provide free clinical treatment to supplement the work of private physicians, 65 per cent provide hospital or other facilities for isolation of dangerous cases, 79 per cent recognize the venereal disease as a major subject in their public health education programs. These statements are largely applicable to smaller cities also. Every state has a bureau of venereal diseases or assigns special personnel for this purpose to its division of

communicable diseases, and provides for diagnostic laboratory aid to physicians and institutions throughout the state.

The notification of syphilis cases in New York State, for example, has risen until it ranks among the first three or four diseases reported, for the years 1921-23 the order of rank was Measles (161,330), Pneumonia (84,879), Syphilis (75,090), Tuberculosis (71,356), Scarlet Fever (67,728).

For the United States 200,584 cases of syphilis were reported to State Boards of Health in 1925, the cost of these cases alone on any basis of estimate produces a staggering sum. Both in private practice and in clinics the treatment of syphilis has shown encouraging gains in the number of patients who remain under treatment until discharged. All of the cities now have general nursing service for venereal disease patients in either hospitals or clinics or in both, and nearly a third have one or more nurses doing field work. Over one half provide some trained social workers for follow-up of patients who discontinue treatment.

The public cost of these advances is reflected in the setting aside of from 1 to 3 cents or more per capita for venereal disease work exclusive of expenditures of hospitals and private agencies. But the real answer to the question "What Price Syphilis?" depends on the basis of calculating the estimates. Whether in terms of dollars, lives, ill health, inefficiency, or social misery, the cost of syphilis will probably outrank that of any other preventable disease. Many studies and careful judgments of syphilologists indicate that 10-15 per cent of the adult population is infected. Hospital surveys of all patients, based on Wassermann tests, show 20 per cent or more, and some institutions have estimated that at least 10 per cent of their entire annual expense is due to venereal diseases, of which cost syphilis is responsible for a large proportion. Perhaps the two outstanding groups of cases for which the work of the physician will count most both for patients and for public welfare are the industrial group and the mothers and infants group. As an illustration concerning the first of these two groups, may be mentioned the valuable and suggestive studies of syphilis in its scientific and sociologic aspects made by Dr. John H. Stokes and Dr. Helen E. Brehmer. They analyzed 3,000 unselected histories of the Mayo Clinic with special reference to syphilis among railroad men and other occupational types. Their findings showed that the disease for that series

of cases was 8 times as prevalent among railway employees as among farmers. For example, Dr Joseph S Lawrence found in his studies 88 per cent of venereal diseases urban, 12 per cent rural in New York State. Dr Stokes discovered that 26 per cent of cases were infected between 17-20 years of age and 32 per cent between 20-25 years, or approximately 60 per cent before the twenty-fifth year of age, while 91 per cent had become infected by their thirty-first year. Such figures have great significance both for the physician and for the public in counting the costs of syphilis—particularly the ultimate costs of missed cases.

Experience seems to warrant the statement that fully 50 per cent of cases are not detected by general medical examination alone, and in 40 per cent or more cases even the Wassermann blood test will probably not be conclusive. Spinal fluid examinations and neurologic findings are evidently essential parts of effective work in detecting many syphilis cases. And all these tests must often be applied in the absence of any history whatever of exposure, or of symptoms directly related to syphilis. The important thing is to get the cases under treatment at the beginning of the infection. For the individual this gives the greatest promise of cure or arrest of the disease, for the public the greatest assurance of successful protection.

Such observations inevitably lead to the conclusion that the medical profession must look with especial care for syphilis among patients from 15 to 30 years of age, and must co-operate in keeping infected cases under competent treatment and observation for long periods of years. This means also inevitably that a large part of the costs must be shared by voluntary agencies and the public, because these expensive and exacting diagnostic and treatment methods can not be paid for fully by many patients and can not be contributed by the physicians alone. The costs of all such work must be added in computing the total price of syphilis to any community or to the nation.

The second group of cases to which I wish to allude in this statement of costs comprises children particularly. Perhaps the greatest tragedy in the whole story of syphilis relates to its attack upon children, and as a matter of the future of the race this is also the basis of its greatest cost. Untold number of infants die before birth or in their first year of life, because of the disease transmitted from their parents, others live on with defective bodies or minds blind or deaf. President Ray Lyman Wilbur in his inaugural address before the American Medical Association said "When we can keep the spirochetes of syphilis out of the body of every new-born babe we shall have added enough to human life and happiness to heal the wounds of the great war." Dr Whittredge Williams found that syphilis con-

stituted the most important single factor in the causation of foetal deaths—being responsible for 34.4 per cent of all deaths in his series between viability and the first two weeks of the puerperium. The results of treatment for both mother and child in such cases has been remarkably encouraging. In general it may be said that when we find evidence of syphilis in one member of a family, we should adopt the principle of studying every member. Dr Solomon says, "One of the saddest points about congenital syphilis is that it is so often unrecognized, through carelessness, indifference, or ignorance of parents, doctors, social workers, or institutions, and thus the beneficent results to be obtained by treatment are lost or delayed to the patient." The earlier the treatment is instituted, the better the chance of preventing disabling symptoms. White and Veeder made intensive efforts to treat and follow up a series of 443 congenital cases. Lack of interest of parents led many to discontinue treatment and only 308 could be followed to the end results. Of these 22 per cent were recorded as cured, 35 per cent improved, 17 per cent unimproved, 25 per cent died. Their conclusion from these unsatisfactory efforts was that at present the most desirable thing to do is to reach the syphilitic woman or mother before or during pregnancy. In other words, many believe that the solution of the problem of hereditary syphilis lies in prevention rather than cure, and prevention in this sense must be applied largely by the practicing physicians and staffs of prenatal clinic service. Whether such service be paid for or given without being recorded in money values, it ought to be estimated and added to the total price we pay for syphilis and its control.

Naturally much effort has been devoted to other phases of prevention. In armies and navies a considerable measure of success has attended chemical prophylaxis measures when carried out with great attention to detail and thoroughness of enforcement. In civil life, however, such measures have thus far proved practically worthless except where physicians as a matter of private practice have directed patients with the same degree of personal care and supervision which is given to those exposed among military forces. Prophylaxis in its larger meaning includes, of course, all other measures for prevention, and much has been done to lessen the opportunities and probabilities of exposure of susceptible persons. The continuous campaign against commercialized prostitution, the growth of protective measures for young people, the development of sound sex education and character training, are all beginning to have their effect. The prevailing opinion among health officers and syphilologists that fewer fresh cases of syphilis occur now than in previous years seems to have much to support it. Apparently the cost of syph-

ilis may be expected to decline markedly in the next ten years

In view of the discussion which is to follow in the symposium this paper need not go into detail regarding any phase of measures for reducing the costs of syphilis, but it may be of interest to summarize the outstanding points in current health department practice for the control of the venereal diseases

I Efforts to find all cases as soon as possible after infection, and to decide in each case what measures will best protect the public from infection

1 *Provision of clinical examination and advice facilities*, to encourage persons who believe that exposure to infection may have occurred to obtain promptly, proper advice and instruction

2 *Provision of diagnostic laboratory facilities* to aid physicians and staffs of clinics and hospitals to make diagnoses of syphilis

3 *Provision of case study facilities* to enable the responsible official or authorized physician to determine on the basis of the circumstances in each case what, if any, special aid, restriction, isolation, or quarantine measures may be required

II Efforts to secure effective treatment of each case with due regard to avoiding the infection of other persons

1 *All necessary assistance* to private physicians, clinics and hospitals, in providing treatment and follow-up service for infected persons

2 *Health department clinic facilities* to supplement so far as may be necessary the venereal disease work of private physicians, clinics and hospitals

III Efforts to inform the public regarding the dangers, modes of infection, and methods of prevention of syphilis and to induce them to apply this knowledge to their protection individually and collectively

1 *Specific instruction pamphlets* furnished to patients and those exposed to infection to ensure understanding of the problem

2 *Health education measures* to inform the general public regarding the dangers and control of venereal diseases (including syphilis)

IV Efforts to obtain and record data related to carrying out the program, and to evaluating the effectiveness of each measure adopted

1 *Reporting of venereal diseases* including syphilis by identification symbol, under such conditions as may prove necessary, according to dangers of transmission of the infection to other persons, in relation to each of the groups of cases classified for action

2 *Supplementing notification by securing follow-up data* on cases discharged from treatment or transferred to other physicians or clinics, on causes for failure to continue treatment, and on other matters concerned with the best treatment of the patient and protection of the public.

3 *Tabulation of data collected for administrative use* of the health officer in reference to prevalence, diagnosis, treatment, cure, infection of others, advice and care for contacts, and to similar problems in the control of the venereal diseases (including syphilis)

It will be seen that for any large measure of success this program must receive the support and hearty co-operation of the medical profession. The serious efforts to study this question as a problem of the private practitioner which have been made by such medical organizations as the Kings County Medical Society, the Academy of Medicine, and medical groups in Syracuse, Cattaraugus County, Buffalo and other cities and counties illustrate how encouraging are the indications that the physicians are determined to do their part in reducing the price of syphilis to the people of New York State. The general co-operation extended by physicians to the venereal disease division of the State Health Department and to the Department of Health of New York City and of other cities also shows how earnestly the members of the New York state association have begun to take up the task of reducing the damage done by this great imitator of other diseases.

This annual meeting and the devotion of one day to syphilis is one of the milestones of progress in this great battle for humanity. With the continued active work and co-operation of the physicians the health departments may confidently expect to bring syphilis under control and greatly reduce its prevalence in succeeding generations.

SYPHILIS IN PREGNANCY *

By ALFRED C BECK, M D

THE diagnosis of syphilis is much more difficult in women than in men. In the male the patient himself discovers the primary lesion. Its characteristics are easily observed by his physician and the specific organism may readily be obtained. Thus a positive diagnosis is made before the appearance of secondaries. Even prior to the discovery of the spirochaeta-pallida and the Wassermann reaction, the diagnosis of syphilis in the male was much easier. A chancre of the penis always led to a keen search for the appearance of secondaries. As a result even mild secondaries usually were observed and the tentative diagnosis of syphilis was confirmed.

In women the primary lesion seldom is found by either the patient or her physician. It has a tendency to disappear rather rapidly and as a rule leaves no scar. In our series of 144 pregnant syphilitic women only 6 gave a history of a primary sore.

Secondary lesions very often are overlooked in the female. Possibly this is due to the fact that they usually have innocent infections. Their sexual life does not lead them to anticipate the luetic consequences of promiscuity. For this reason, together with the fact that primary lesions seldom are evident, mild secondaries often pass unobserved. To repeat—*the man anticipates his syphilis. He looks for it and he finds it when it appears. The woman does not anticipate her infection. She does not look for it and usually does not observe it when it appears.* History and physical examination in our 144 syphilitic women revealed the presence of luetic lesions in only 34 cases.

Syphilis in women is best discovered by its effect on the products of conception. Pregnancy in untreated cases usually terminates in the birth of a dead macerated fetus or a living syphilitic infant. History of the previous pregnancies is perhaps the most valuable data that may be obtained for diagnostic purposes. 95 of the 144 syphilitic women had been previously pregnant. In 71 or 74 per cent of these the various pregnancies terminated as above. Occasionally all of the pregnancies will go to term and result in the birth of apparently healthy children. Upon investigating such families we have found that most of these supposedly healthy children have syphilis. We, therefore, cannot rule out syphilis when the patient tells us that all of her pregnancies went to term and resulted in the birth of healthy children. We must rule out congenital syphilis in these apparently healthy children before we may assume that the patient was free from syphilis at the time of her previous pregnancy.

The routine Wassermann test is of inestimable

value in our work. Whenever a patient's blood is strongly positive and the patient's history is otherwise negative the test is repeated in order that we may eliminate the possibility of laboratory error. While we admit that occasionally a patient's blood may be strongly positive during pregnancy and may become negative after delivery, even though she received no treatment, we do not let this fact influence us in the management of our cases. We therefore treat all of our patients vigorously even though no evidence of syphilis other than the Wassermann is present at the time, since we have found that investigation of the husband and the other children as well as subsequent events usually prove that the patient undoubtedly has syphilis.

In our clinic it is rather difficult to obtain blood for the Wassermann reaction from the husbands of our patients. Only 51 of the 144 husbands co-operated with us in this respect. Forty-two of these had a positive reaction.

TREATMENT

It is our custom to begin anti-syphilitic treatment as soon as the diagnosis is made irrespective of the period of gestation. We give 6 intravenous injections of salvarsan at weekly intervals. At the same time intramuscular mercury injections are started and continued for a period of 12 weeks. If, after this course of 6 salvarsan and 12 mercury injections the Wassermann is still positive, a second similar course is given. If the reactions are severe the dose is diminished. The urine should be observed very carefully while the pregnant woman is receiving salvarsan. Albuminuria or evidence of toxemia should lead to either temporary discontinuance of treatment or a diminution in the dose. One of our patients died two days after she had received the usual dose of salvarsan. It was impossible to get an accurate history of her condition subsequent to the time of her last treatment. From the meagre information that was obtained, we feel that she died of a fulminating toxemia possibly secondary to renal damage caused by the salvarsan. The clinical picture was not that observed in salvarsan poisoning.

Immediately after the delivery of our syphilitic patients their infants are referred to the department of pediatrics by whom they are treated and observed throughout their infancy.

END RESULTS

The 144 syphilitic women included in this series were cared for by our service during a part or the whole of 166 pregnancies. All had

3 *Tabulation of data collected for administrative use* of the health officer in reference to prevalence, diagnosis, treatment, cure, infection of others, advice and care for contacts, and to similar problems in the control of the venereal diseases (including syphilis)

It will be seen that for any large measure of success this program must receive the support and hearty co-operation of the medical profession. The serious efforts to study this question as a problem of the private practitioner which have been made by such medical organizations as the Kings County Medical Society, the Academy of Medicine, and medical groups in Syracuse, Cattaraugus County, Buffalo and other cities and counties illustrate how encouraging are the indications that the physicians are determined to do their part in reducing the price of syphilis to the people of New York State. The general co-operation extended by physicians to the venereal disease division of the State Health Department and to the Department of Health of New York City and of other cities also shows how earnestly the members of the New York state association have begun to take up the task of reducing the damage done by this great imitator of other diseases.

This annual meeting and the devotion of one day to syphilis is one of the milestones of progress in this great battle for humanity. With the continued active work and co-operation of the physicians the health departments may confidently expect to bring syphilis under control and greatly reduce its prevalence in succeeding generations.

to call them such, contribute to the delay of treatment in the early cases. The first of these is the practice of making diagnoses on the clinical appearance of the primary lesion, in the belief that chancre and chancroid can be distinguished from each other by physical characteristics. So dangerous do I believe this notion to be that I decline to teach or to allow my medical students to learn that there is any way to tell the one from the other except by laboratory methods. It is, I believe, a sound cardinal principle to make no final diagnosis of chancroid, until four months have elapsed from the onset of the genital lesion. It is equally cardinal not to treat as syphilis any lesion which is not demonstrably such (darkfield or Wassermann test, or both) unless one is prepared to follow through the full procedure for syphilis. In the doubtful case, observation for syphilis and local treatment for chancroid only after all means of immediate diagnosis of syphilis have failed, becomes the rational practice. Every genital lesion is thus potentially a chancre until it is finally proved otherwise by time and laboratory tests. Such reversal of the orderly forms of the past will be disturbing to the settled mind, but its practical virtues will, I feel confident, be demonstrated by the coming generation. Exhaust every resource, then, to make a diagnosis of syphilis, if all local laboratory tests fail, begin treatment for chancroid, but repeat the blood Wassermann test at short intervals for four months.

The second misconception involves the use of arsphenamine before the appearance of the secondary eruption. It is impossible here to go into the arguments which have been advanced to discountenance the use of arsphenamines in early syphilis on the ground that they interfere with the development of the patient's resistance or immunity mechanism. Such objections to arsphenamine are based, so far as I can determine, first, upon a decade of improper or insufficient use of the drug and failure to use it in proper combination with mercury, and, second, upon a misconception of the value of the body's defense mechanism against untreated syphilis. If arsphenamine and mercury are properly used in combination, the difference between what the unaided defense and the best modern treatment can accomplish appears to be the difference between 05 per cent arrest without treatment, and 64 to 97 per cent arrest with treatment. Mercury by mouth, to which the conservatives pin their faith, seemed in a study of several hundred cases which I made with DesBrisay to have yielded 10 to 18 per cent arrest. Nor does there appear to be any convincing evidence that effective modern treatment is responsible for an increase in neuro-syphilis as is sometimes contended. Ineffective, desultory, unsupported use of the arsphenamines is dangerous. But even this is not half so dangerous to

the public health, or even to the individual himself, as is the withholding of this drug from the patient with early and infectious syphilis.

Obsolescence of the "Abortive Cure"—The literature of the first five years of the arsphenamine era reflects constantly the conception that syphilis is in the early days or weeks of its course, a local disease, confined to the chancre and its adjacent lymphatics. Up to 1917, clinicians have remained in practical ignorance of Neisser's and Brown and Pearce's demonstration that the disease is a general infection, with organisms present in the bone marrow, spleen and testis, within a few days after its invasion of the body, and days or even weeks before the appearance of the chancre. This concept of a local infection led to the notion of an easy abbreviated or shortened "abortive cure." Most of the figures on therapeutic results presented in the great survey of the German Dermatologic Congress in 1921 deal with short courses and abortive cures. It would appear that one of the first duties of the modern syphilotherapist is to stop the leaking of "uncured" cases through this misconception of a local stage of the syphilitic infection, and to make the modern slogan, "Treat to maximums, not minimums." We may wisely cease to consider that there is an easily cured, a benign, trivial or local syphilis, for there is no possible way of demonstrating its existence in any given case, and all the evidence is against there being any considerable proportion of such cases. Let us rather think of all early syphilis as severe, grave, worthy of our utmost efforts and the patient's best cooperation, and "treat to maximums," as if each case were the worst with which we had ever been called upon to deal.

The Problem of the Rest Interval in Early Syphilis—One of the most interesting features of the forthcoming publications by Moore and Kemp of the treatment results obtained by them at the Syphilis Clinic of the Johns Hopkins Hospital, is their evidence that superior results are obtained by doing away entirely with rest intervals in the treatment of early syphilis. As one who has long contended that the early infection must be under one or another kind of effective treatment continuously throughout the first two years, this demonstration is to me especially gratifying and convincing. It appears from their study that the keeping of the patient on alternating mercurial (inunction) and arsphenamine treatment has a strikingly better effect on the Wassermann curve than have intermittent procedures involving periods of complete rest from all treatment. Treatment studies by Becker and myself, while not directly concerned with this question, supported the desirability of a similar system from the standpoint of ultimate results. I think it sound, therefore, to commend to you such a scheme of treatment for your early cases.

strongly positive Wassermans as well as other definite evidence of syphilis. No cases, therefore, are included in which the diagnosis was based solely upon serological findings.

Thirty-three of our patients went into labor before salvarsan could be given. Nine of these gave birth to living syphilitic infants and 16 resulted in still births. Eight or 24 per cent of these 33 untreated pregnant women gave birth to living children which showed no evidence of syphilis.

At least one course of anti-syphilitic treatment was given to 76 women. Sixty-four or 84 per cent of these went to term and were delivered of apparently normal infants. Of the remaining 12, 6 gave birth to living syphilitic infants and 6 terminated in still births.

From 1 to 5 injections of salvarsan were given to 57 cases. Forty or 70 per cent of these terminated in the birth of apparently healthy infants. Ten had still births and 7 were delivered of living syphilitic children.

Some of the infants included in this series have been under observation 7 years. In only two instances have children which were healthy at birth shown evidences of syphilis. In one the Wassermann became positive at four years of age. The other died of syphilitic meningitis when it was three years old. Only careful observation over a long period of time will lead to an accurate opinion as to the prognosis in these cases.

SUMMARY

History and physical findings aided in the diagnosis in only 23.5 per cent of our cases.

74.7 per cent of the women who had been previously pregnant gave a pregnancy history which was suggestive of syphilis.

Occasionally syphilitic women carry all of their pregnancies to term and give birth to living infants. Careful observation shows most of these infants to be syphilitic. Syphilis therefore cannot be ruled out when a patient states that all of her children are living and well.

The Wassermann reaction is a most valuable aid in the diagnosis of syphilis during pregnancy. The so-called false positive Wassermann due to pregnancy usually is real and other evidences of syphilis can be found if a careful investigation is made.

Salvarsan should be given as soon as the diagnosis is made irrespective of the period of gestation.

Eighty-four per cent of the women who received six or more injections of salvarsan gave birth to living infants which have shown no evidence of syphilis.

Prognosis as regards these apparently non-syphilitic infants must be guarded.

(I wish to acknowledge my indebtedness to the genito-urinary and pediatric departments of the hospital for their co-operation in the care of these patients.)

PROBLEMS AND METHODS IN THE TREATMENT OF SYPHILIS

By JOHN H. STOKES, M.D.

Professor of Dermatology and Syphilology, School of Medicine, University of Pennsylvania

WHAT are the critical problems and the accomplishments of modern treatment methods in syphilis? Speaking categorically and didactically, and with apologies for the lack of discriminating shading unavoidable in a fifteen-minute summary, I should say that they are these:

A Justified Emphasis on Early Treatment of Early Syphilis—For more than a decade, the syphilologist has preached *a priori* the importance for the "cure" of syphilis of days, hours, and minutes gained in the treatment of the chancre and secondaries by the utilization in diagnosis of the darkfield and recently of the local or tissue Wassermann test. The demonstration in actual figures, of what it means to the patient to receive his first injection of arsphenamine and his first course of treatment while the Wassermann reaction is still negative on the blood, has, however, had to await the accumulation of reports from clinics all over the

world, which only now are beginning to assume a sufficiently final quality to permit of sound discussion. It is now possible to say with quite reasonable accuracy that to fail to make a diagnosis, or to delay or withhold treatment from any patient with early syphilis, until the blood Wassermann reaction has become positive, makes approximately the difference between a 92 to 97 per cent outlook for radical cure, and a 64 to 75 per cent outlook. The physician, therefore, who through lack of proper equipment or training, or through misconceptions regarding the morphologic diagnosis of the chancre or the alleged dangers of arsphenamine, withholds effective treatment until the blood is positive and the secondary stage established, has cost his patient about one-fourth of his chance for complete recovery.

Two current misconceptions, for I make bold

* From the Department of Dermatology and Syphilology, School of Medicine, University of Pennsylvania.

of physical diagnosis have too long paraded their autopsy studies of advanced aortic regurgitation and photographs of perforating and ruptured aneurysms, and discourses on symptoms and signs expressive of our own diagnostic shortsightedness rather than any virtuosity in the detection of disease. The emphasis of the future, if we are to perform our preventive duty in treatment, must be on earlier warnings—on the accentuated ringing harshening aortic second sound, the fluoroscopically detected early dilatation of the aorta, and the aortic presystolic murmur, rather than on the *cor bovinum*, the capillary pulse, the diastolic murmur and the thrill. The best results in cardiovascular syphilis (and it is indeed the ubiquitous syphilis of later years) are only obtainable in early cases. Let us then increase the proportion of such cases by the most suspicious alertness and the most determined observational control.

Observational control itself is the great problem of modern syphilotherapy for upon it depends, at one and the same time, the protection of the patient from the uncertainties of what we often too rashly call "cure," and the evaluation of our own treatment results. We shall do the cause of effective treatment for syphilis nothing but good if we speak in terms of arrest, not "cure," for of the latter there is no convincing standard. We shall advance knowledge a century in a decade if today we begin to insist for every person with syphilis on observation throughout life.

A problem which is doubtless very real to many of you concerns the possibility of an increasing resistance on the part of syphilis, as a disease, to the treatment measures which we bring to bear upon it. With the majority of physicians this takes the form of increasing complaint about the fixed or resistant positive blood Wassermann reaction in the early case, the patient who by all the gods and guide-books, should be cured by what we have done for him. There is a real issue here, but complicated of course by the fact that few practitioners are using the methods which published work is showing will produce the best possible results. Some syphilis will in all probability relapse, no matter how treated, and more of it will fail of cure as long as relatively less effective arsphenamine derivatives and second-class insoluble mercurials displace the most powerful drugs in our armamentarium. But even discounting the wholesale deficiency of much that passes as modern treatment for syphilis, the spokesman (Silberstein) for one of the most effectively organized clinics in Europe (Scholtz clinic), whose treatment methods and results stand critical examination, believes that there has been a definite increase in the resistiveness of syphilis as measured in the persistent positive blood Wassermann test. Silberstein finds that 23 per cent of cases today become irre-

versible to the Wassermann test by the use of methods when ten years ago were producing 100 per cent of reversals. The possibility that syphilis may turn our flank in this fashion is well supported by experimental evidence (Klauder). What course then shall we pursue with the patient who presents an irreversible or relapsing fixed positive blood Wassermann reaction? While to some extent we may regard him as the possessor of an active defense mechanism, and hence favored rather than the reverse, my clinical advice based on several surveys, would be to regard him as the unfortunate possessor of an obstinate infection, likely to attack his cardiovascular or his nervous system if it has not already done so. Every patient with a fixed positive Wassermann reaction should have a spinal fluid examination before his situation is even discussed, and should be kept under observation by an expert heart man from year to year, especially after the fifth year of his infection. As treatment for the fixed positive Wassermann, first of all, treat all early syphilis long and energetically. Then utilize the principle of varied attack, and shift from one arsphenamine to another, giving bismuth determinedly in alternation with more effective mercurials (soluble salt) and as a last resort trying perhaps the effect of fever therapy, either as non-specific protein shock, or by malarial infection.

The marriage of the patient with syphilis offers one of the genuine problems of this as of all other eras in which syphilis has beset mankind. We are all familiar with the five-year rule, and the injunction that a patient must be symptom-free for two years before marriage is permitted. If I were categorically to summarize my warnings on the matter, I would say, never base a permission to marry solely on a Wassermann test, and especially do not trust a negative test or repeated negative tests in an early case as a guide to the resumption of unprotected intercourse. Do not trust appearances in the woman, for she may be a carrier of infection to the child months or years after all clinical and serologic evidence of syphilis has disappeared. Do not trust shortened treatment courses, or "modern methods." Try to introduce all the time possible between the day of infection and the day of marriage, for time is the great sterilizer in syphilis. And finally, use common sense. Try to keep syphilis in the family, so to speak. Advocate a "precautionized marriage," if marriage there must be, not with abstinence, which will rarely be practiced, but with protection, contraception, preconceptional treatment, and prenatal treatment of the expectant mother.

Recent Advances—Bismuth—Completely to express oneself in this tabloid fashion on so important a drug is of course impossible. Yet a few principles are beginning to stand out in regard to its use. It should not be regarded as a

as will keep them continuously under the influence either of arsphenamine, mercury, or bismuth during the first year, with sufficient overlapping in the form of simultaneous use of two drugs, to insure that the patient does not relapse while his immunity is being built up by the slower acting agents in the group

The Value of Prolonged Treatment—Another substantial result of the modern evaluations of treatment now in process of publication from various sources, is the re-demonstration of an old principle—that syphilis is a disease which is worn out, rather than crushed. Our over-confidence in the miracle-working powers of chemotherapy has for a time eclipsed this still most fundamental rule of syphilotherapy. Moore and Kemp have furnished its most massive demonstration in relation to early syphilis. They found in a study of more than 400 cases, half of which had been observed for three or more years, that with seronegative primary syphilis, in which the patients received one to eight injections, relapse occurred in 76 per cent of cases, following six to twelve injections, relapse in 54 per cent, following thirteen to twenty injections, relapse in 14 per cent, and following twenty-one to forty injections, no relapse whatever. No prettier demonstration of the value of prolonged intensive use of arsphenamine and mercury could be asked. In seropositive primary syphilis, and florid secondaries, the figures are confirmatory both of the value of prolonged treatment and of the greater incidence of relapse once the patient becomes Wassermann positive. Following one to eight injections in florid secondary syphilis likewise, for example, relapse occurred in 90 per cent, after six to twelve injections, in 67 per cent, after thirteen to twenty injections, 48 per cent, and after twenty-one to forty injections, 23 per cent. Becker and I in a smaller group (116 cases) were able graphically to indicate the same facts, and Mutschler has published an interesting comparison of the better results obtained with two courses of twelve injections as compared with one course. In another aspect of syphilis, namely, prenatal or heredosyphilis, I was similarly able, in a survey of two hundred cases, to demonstrate the steady rise in the proportion of good and excellent results with prolonged treatment in what is essentially an aspect of late syphilis. I think, then, that it may be safely proposed as a guidepost to modern treatment methods, that not one arsphenamine course, but three or four, and not three or four injections, but six, eight, and ten per course, should be our ordinary requirement, more or less irrespective especially of the blood Wassermann findings, to which too many of us too readily pin our faith.

The Weak Points in Modern Syphilotherapy—No longer limiting ourselves to the field of early syphilis, consider for the moment the outstand-

ing shortcomings of our modern therapeutic practice. Among the general sources of difficulty, especially in late syphilis, I should rate the practitioner's unfamiliarity with the "therapeutic shock" or Herxheimer reaction, as one of the commonest. The first injection of an arsphenamine inflicts upon the syphilitic patient at all stages of the disease, a pronounced shock due to the flaring up of the local process by irritation of the organisms present. If this shock occurs in vital structures such as the nervous system or the circulatory system, serious or even disastrous results may ensue. Hence the practitioner should learn to prepare patients who have sustained such involvements with mercury or bismuth and the iodides, a slower approach, before he begins the use of the arsphenamines, if he wishes to reduce treatment complications and ultimate damage to a minimum. One could almost make it a safe rule never to begin the treatment of syphilis acutely involving the special sense organs, the brain, the heart and coronaries, the aorta or the liver, with arsphenamine. They should all be "prepared" with mercury or bismuth.

The second source of difficulty is the therapeutic paradox, aptly so named by Wile, in which the patient, with a serious involvement of an important organ following the use of such a drug as arsphenamine, is made worse or dies of the "cure" of his disease, his structures unable to compensate for the healing changes too rapidly induced by treatment. The heart and the liver are conspicuously affected by this too often disastrous situation, whose remedy, as in the case of therapeutic shock, is, of course, the slow preparation of the patient with iodide and mercury, or perhaps bismuth, before, or even altogether in place of, arsphenamine therapy.

A third source of difficulty concerns the comparatively late stage at which the two major problems of modern syphilology—involvement of the nervous system, and of the cardiovascular system—come to clinical recognition. The emphasis of medical teaching in neurology in the past has been upon the fixed pupil and the absent knee jerk, the grandiose delusion and the apoplectic form seizure in neurosyphilis, rather than upon that infinitely more vital asymptomatic period in which only the spinal fluid, or the fundus of the eye, displays the warning of what is to come. Systematic early and repeated examination of the spinal fluid must, therefore, be practiced by the physician not as part of diagnosis in late syphilis, but as part of treatment in early syphilis, if the possibilities of our modern therapeutic methods are to be realized to the full. It is a sound rule that no practitioner is adequately managing a patient seen with chancre or secondaries, who has not insisted on a complete spinal fluid examination within the first year. So also in cardiovascular syphilis, the text-books

The treatment of the tardive heredosyphilitic patient and especially of those with interstitial keratitis can be greatly intensified, with admirable results, as shown by the recent study of Carvill and Derby, who succeeded in protecting the second eye from involvement, a hitherto almost unheard of feat in 19 per cent of cases, and reduced the incidence of relapse from 27 per cent to 36 per cent. Ophthalmologists who have minimized the value of the arsphenamines in particular, in this condition, have surely not employed the drugs in accordance with modern standards. The combined use of arsphenamine (606), a soluble mercurial or bismuth, and large doses of iodine (60 to 150 grains a day) can produce results of the very first order in this heretofore most intractable and crippling complication.

The Results of Treatment—In the treatment of syphilis results are so distinctly the product of methods, that one hesitates to present accomplishments without a full discussion of the procedures by which they were obtained. It may, however, stimulate you to a renewed confidence in your potential grasp of the situation, and a renewed energy in study and observation, if I briefly epitomize the statistical experience on which I base the statement that I regard syphilis as a genuinely treat infection. In early syphilis, as I have said, effective treatment, available to any patient, produces, so far as present knowledge will carry us, 75 to 100 per cent "cures." In syphilis of the late types, results are modified by the scars and residua of the disease. Yet in spite of this, syphilis of the bones yields more than 90 per cent excellent and good results from both clinical and serologic standpoints. Syphilis of the stomach yields 79 per cent excellent and good results, syphilis of the liver under persistent careful treatment (and no visceral aspect of the

disease has a poorer outlook), 58 per cent excellent results and 80 per cent improved, and heredosyphilis in all its aspects is slightly improved in 83 per cent and attains excellent and good results in 59 per cent. In interstitial keratitis, a study based on a comparatively unfavorable material, late in coming under treatment, showed improvement aggregating 66 per cent. In neurosyphilis, long the accepted Waterloo of syphilotherapy, recently reported results without tryparsamide include 91 per cent excellent and good results in meningeal (early) cases, 74 per cent in cerebrospinal syphilis, 48 per cent excellent and good results in tabetics, with improvement in 85 per cent, and poor results in vascular and parietic neurosyphilis. The late Dr Fordyce reported in meningo-vascular syphilis, 79 per cent improved and 32 per cent "cured", and in tabes dorsalis 25 per cent cured and 83 per cent improved. The rule of no results by modern methods in paresis was broken by the advent of tryparsamide, in which asymptomatic paresis (serologic paresis or paresis sine paresi) yielded to three different groups of investigators, results ranging from 80 to 100 per cent good, and early symptomatic paresis results ranging from 35 to 60 per cent good. Using only the often invoked blood Wassermann criterion, 94 per cent of early cases in our experience become Wassermann negative after from twelve to twenty-nine arsphenamine injections, and ninety injections, and 78 per cent of latent, late and hereditary cases with an average duration of 13 years, were made negative on the blood with the same treatment. Here, too, as in all treatment results in syphilis, there stands out that most fundamental and all-inclusive of principles—which I offer as the alpha and omega of modern syphilotherapy—treat early, treat repeatedly, treat long.

substitute for arsphenamine, bearing in mind Kolle's observations on its spirochetostatic character rather than its spirillicidal value. It holds the infection at a standstill, perhaps, rather than aborts it. Nor is it yet the completely authorized successor of mercury, as some would have it, though it certainly shows promise in this direction. I am inclined to advocate its alternation with mercury in early syphilis without reduction in arsphenamine standards, and to urge its value in dealing with all resistant infections and its good effect as preparatory treatment in neurosyphilis and cardiovascular syphilis. It is very gratifying to witness the rapidity with which an infection that has withstood ordinary and even intensive measures, will be reduced to serologic negativity under bismuth. It is important to know, as Warren has shown, just how much metallic bismuth there is in the preparation one uses, and many results both pro and con will need revision in the light of such information. The tartrobismuthate, the hydroxide and the iodoquinat apparently lead in popularity at the present time.

Tryparsamide—No discussion of the modern treatment of syphilis could be complete without some mention of this remarkably interesting and important drug. The fear of eye complications from its use is being too widely influential, if anything, in limiting the application of what is in reasonably experienced hands, a veritable miracle-worker in the treatment of resistant neurosyphilis of the pre-paretic and parietic types. The drug is not directly spirillicidal to any significant degree, and hence has no place whatever in the treatment of early syphilis, even of the nervous system (primary and secondary stage). Its action seems to be that of a resistance builder and a tonic. The transformation that it affects in early paresis, with a minimum of cost and inconvenience to the patient, is a veritable god-send when contrasted with the discomforts and impracticality of malarial therapy under American conditions. On the other hand, in the institutional type of parietic, malarial inoculation is apparently superior. The eye complications of tryparsamide are of minor importance in patients with normal eyes, and in the hands of one experienced with the drug, can be practically reduced to zero by proper interpretation of symptoms and the taking of perimetric fields and visual acuity tests after each injection of the first course. Even if slight trouble appears, recovery is the rule, and the drug may then, after a lapse of a month, be resumed. Remember, in connection with tryparsamide, that the longer it is used the more favorable the impression it makes, and do not expect to have a sound opinion at the end of a course or two. In comparing it with malaria, likewise recall the intrinsic complications and a mortality approximating 10 per cent in

malarial therapy, which seems to make it a last rather than a first resort.

Fever Therapy—This aspect of treatment for syphilis has an interesting and, if one would wholly accept the Viennese view, a glowing future. It is a phase of the non-specific attack on the disease which is certain to be better understood in the next decade, as the era of chemotherapeutic enthusiasm undergoes the critical evaluation of time. The contest between specific and non-specific therapy will continue to be a hot one, and who can say when the chemists will produce the ideal antisyphilitic drug, free from all heavy metals and poisonous radicals, non-toxic, delicious as a relish when served with food, and of such potency that a single dose, by mouth, once taken and fixed in the tissues, insures absolute immunity from antemortem syphilis and postmortem disclosures for all time to come.

Prophylaxis, which is in a sense, anticipatory treatment, has perhaps a future worth watching. In the form of arsphenamine administered to the person who has been exposed to syphilis within a day or two after exposure, several observers have rendered excellent, some less critically commendatory reports. The syphilologist is in sympathy with every effort to abort the syphilitic infection before it has gained a definite foothold, but he still contends that if the beginning of treatment is advanced, its certainty shall not thereby be jeopardized. All arsphenamine prophylaxis must, therefore, be carried to the point of adequate treatment for an early infection if any considerable uncertainty as to cure exists. I should say that the deadline should for the time being be drawn at the third day after exposure. After this, arsphenamine as prophylaxis is untrustworthy. Such a procedure as the routine treatment of all genital lesions for syphilis without diagnosis seems to me as yet too advanced for support.

Of other aspects of prophylaxis, I would urge upon you a study of the value of prenatal treatment of the mother with syphilis, for the protection of the child. While one hears at times a dissenting voice, the consensus is that a great reduction of the incidence of syphilis in the child can be brought about by intelligent management of the infected mother. She should be treated for syphilis with moderate (not extreme) intensity, using both neoarsphenamine and bismuth, from the time her infection is discovered to within a month of delivery. Once delivered, her treatment should be continued to prevent relapse, and the child, whether with symptoms or without, should be watched over a period of months and years, not days and weeks, for signs of infection. The treatment of the heredosyphilitic child has been rendered much more practical for the average physician since the advent of sulpharsphenamine and the excellent intramuscular technic of Fordyce and Rosen.

intensive treatment in cases in which the syphilitic tumors are associated with extensive cirrhosis of the whole organ

Particularly difficult I believe are the occasional cases of syphilis and cancer existing in the liver at the same time. I have seen two such cases in which a clear cut differential diagnosis seemed impossible with existing criteria

Of great interest and seeking early solution is the relation of pre-existing syphilis to the general syndrome of hypertension. It would appear at least from present knowledge that a most paradoxical condition of affairs exists in this field. Syphilis, the great producer of arterial damage in both great and small vessels, attacking almost by predilection heart muscle and blood vessel wall, plays but a small role in the clinical pictures of general arteriosclerosis and hypertension

The apparent infrequency of severe early damage to the kidney in syphilis may account for the apparent insignificant role of syphilis in the etiology of general arteriosclerosis. Recent observation, however, would seem to show that syphilitic nephritis is not so uncommon as was previously believed and undoubtedly other factors than the freedom of the kidney must be brought to light to account for the failure of syphilitic sclerosis to produce hypertension. The soundness of this present day view, at least as borne out clinically, should be thoroughly investigated and if true its cause ascertained

An absorbing problem, not only as it bears upon the present problem, but in its relation to the general question of cancer etiology, is the relation of old syphilitic lesions to visceral carcinoma. The frequent association of syphilitic proctitis, that is ulcer, stenosis and stricture, to rapidly developing rectal cancer, cannot be regarded as accidental or coincident. That a causal relation between malignant epithelial degeneration and pre-existing syphilitic injury to the part exists is borne out by the greater frequency of the same chain of events in the mouth, tongue and pharynx

With the recognition during the past few years of a much greater incidence of gastric and intestinal syphilis, the possible relation between such lesions and gastric cancer would also seem to merit investigation. The solution of the problem of this relationship no doubt lies in the determination of whether the spirochaete itself may be a factor concerned with epithelial metaplasia or whether the association is merely one of disordered epithelium or prepared soil, readily becoming malignant in a break in normal epithelial continuity

A field still untouched and demanding early study is the determination of proper criteria for the clinical diagnosis of pulmonary syphilis. At present, such a diagnosis is of necessity, a post-mortem one. That the condition exists we know,

that its diagnosis is next to impossible according to present day knowledge lies in the fact that the picture of pulmonary syphilis, ordinarily speaking, is that of pulmonary disease. Laboratory criteria other than the autopsy offer little help, nor does the X-ray give us reliable data for a diagnosis of pulmonary syphilis. A pulmonary syphilitic lesion may present itself with nothing more distinctive than with the symptoms of massive consolidation, of diffuse fibroid change, of cavitation or bronchiectasis, simulating exactly pulmonary neoplasm, unresolved pneumonia, lung abscess, bronchiectasis or any phase of pulmonary tuberculosis

With the widespread incidence of tuberculosis and syphilis it is inevitable that the two frequently co-exist. To establish, however, trustworthy signs of syphilitic pulmonary disease, knowing that such can exist with or without tuberculosis, constitutes a real problem for the internist and from the patient's standpoint, it calls for early elucidation

Lastly, the relation of syphilis to diseases of the hematopoietic system and to the production of various types of anemia must be considered as a problem deserving of considerable study. Acute lysis of red blood cells is an occasional accompaniment of early syphilis. The degree of resulting anemia may be sufficiently extreme to simulate secondary anemia from other cause. Early and late syphilis of the spleen and bone marrow may produce pictures strikingly like those of the so-called primary anemias and of pernicious anemia. The occasional prompt and splendid recovery of such cases under anti-syphilitic regime, in the presence of a syphilitic background, constitutes more than presumptive evidence of their syphilitic nature. There remain, however, those cases in which syphilis is merely an accidental finding and still others in which the syphilitic background plays a secondary contributory, but not causal role. In neither of two last named groups does anti-syphilitic treatment result in benefit. Embodying as it does the use of heavy metals, which are themselves occasionally hemolytic, in the first group at least such treatment might be harmful. A comprehensive study of the syphilitic anemias with a view to establishing the role of spirochaetal infection as etiologic in some cases and casual in others merits early and intensive study

The solution of these problems will come I believe not with newer instruments of precision or with the establishment of new laboratory methods, but by the careful observation of many cases, coupled with the renaissance of the fine qualities of clear clinical observation which characterized the clinician of the day when diagnoses depended solely upon the exercise of a judicious mind, fortified by the impression of five highly trained senses

SYPHILIS FROM THE STANDPOINT OF THE INTERNIST

By UDO J WILE, A B, M D

Professor of Dermatology and Syphilology, University of Michigan Medical School.

THE establishment in 1905 of the infecting organism of syphilis and the elaboration shortly thereafter of the biologic diagnostic test have created what may be termed the newer pathology of syphilis. Resting upon a sound pathologic basis, Clinical Medicine has been enormously enriched in all its fields by the inclusion into the syphilitic picture of many clinical entities which previously had no sound foundation or established place in the natural history of the disease. In no other field of medicine has the periphery of our knowledge been extended further through the newer pathology than in the field of Internal Medicine. The definite demonstration of spirochaetes and syphilitic changes in aortitis, in most of the cases of aortic regurgitation, in many of myocardial disease, coronary disease, and aortic aneurism, have added these clinical pictures, which are but a few of many others, to the internist's broadened viewpoint of spirochaetal infection.

The whole problem of syphilis, however, from the standpoint of the internist, has not been simplified to the extent that one might first suppose, by the inclusion into it of these and other hitherto obscure conditions.

The occasional happy therapeutic result attendant upon antisyphilitic treatment in diseases of obscure etiology, in which syphilis is known to occur as a coincident infection, lead naturally to the inference that the syphilis may have more than an accidental role and that indeed it may in some cases at least be the causative factor. Of equal significance are those conditions in which infection, not necessarily specific, is the etiologic factor in profound parenchymatous disturbance, and in which syphilis can and does occasionally play the role of any other acute infectious process.

The necessary brevity of this essay does not permit of anything save mere mention of some of the newer problems which face the internist and clamor for solution, and which follow naturally in the wake of the broader concept of syphilis from the internist's standpoint.

In thyroid disease associated with syphilis we may be dealing with a mere coincidence of the two diseases in no way related, or syphilis may be the direct cause of a thyroiditis with or without the hyperthyroid state. Finally, the infection from syphilis may be the insult giving rise to hyperthyroidism, bearing the same relation to the latter that any other acute infection does. To properly evaluate an existing syphilis in the hyperthyroid state and in occasional cases of hypothyroidism requires the exercise of the greatest clinical judgment. The need for such careful

evaluation is self-evident. The cases of true syphilitic thyroiditis, such as gumma of the thyroid and in not a few of those cases in which hyperthyroidism appears with the syphilis as the important etiologic factor, are markedly benefited by antisyphilitic treatment, paralleling the prognosis of the best medical and surgical cures. In those cases on the contrary in which the two are mere coincidental conditions with no etiologic relationship, antisyphilitic treatment has no beneficial effect and may indeed be deleterious.

The need for the exercise of the same critical judgment exists when diabetes and syphilis co-exist. With the widespread incidence of both diabetes and syphilis, their occurrence together in the same patient should be regarded a priori, as a casual rather than a causal relationship. However, it should be recalled that syphilitic pancreatitis is invariably a glycosuric syndrome, whether the pathology is in the form of isolated gumma of the head, of the pancreas, or diffuse syphiloma and sclerosis of the entire gland. Under these conditions it occasionally becomes necessary to consider syphilis in the etiology of an evident diabetes. Here again brilliant therapeutic results may follow the recognition of the syphilitic syndrome and it is particularly in such cases where dietary regime and other forms of treatment would fail. The well-known imitative quality of spirochaetal infection is in no condition better illustrated than in cases where it leads to the production of an apparently typical diabetes mellitus.

To the pictures of hepatic syphilis and their relation to the cirrheses, much has been added to clear up the confused pathologic and clinical symptom complex of liver disease, but much remains to be cleared up. It may be accepted that syphilis can portray in the liver almost any pathologic and clinical syndrome from acute yellow atrophy to hypertrophic cirrhosis. Many of the clinical pictures described as entities are merely phases in point of time of the same process, and much confusion results from failure to so interpret them. A large liver with or without ascites and with hypertrophy of the spleen may so appear to one clinician and the same case appear at a later date to another as hepatic lobatum or cirrhosis with atrophy. In no organ apparently do large gummas appear and disappear so readily with or without symptoms as in the liver. The entire picture of extensive gummosis hepatitis can undergo kaleidoscopic changes in an incredibly short time. Within a few weeks the picture may vary from apparent enormous increases in size of the liver without ascites to ascites and a constricted liver, as the result of injudicious

THE VALUE OF THE SYPHILIS EXHIBIT

The syphilis exhibit of the Medical Society of the State of New York aroused emotions of various kinds and degrees in those who studied it. At one extreme there were those who were overwhelmed by the extent of the ramifications of the disease, and felt helpless at the sight of its extensions into every organ of the body and its imitation of almost every pathological condition. They recoiled from the very immensity of the problem, and were depressed by their inability to understand it all. To these persons, syphilis is a problem that belong to a narrow specialist, and that does not concern the general practitioner of medicine.

At the other extreme were those who took in the whole exhibit at an hour's glance, saw the obscure problems in diagnosis and treatment made clear, and gained the idea that after all syphilis is easy to understand and handle. These persons will go home and will diagnose every obscure condition as syphilis—until they see a demonstration on tuberculosis when all their diagnoses will be incipient consumption.

Between these two extremes a considerable number of thoughtful doctors hold a middle course and are neither indifferent nor over sanguine. They are awed by the numberless manifestations of the disease and will approach its diagnosis with faith and prayer—for it is a serious matter to fail to recognize syphilis when it exists, or to diagnose a case as syphilis when it is not.

The great value of the exhibit was that it revealed syphilis as an entity. A doctor is apt to be like any one of the blind men who described

an elephant as a tree, or a rope, or a snake, according to the part they happened to touch. Those doctors who have seen the manifestations of syphilis in only the skin and bones will gain a more true conception of the disease if they stand where they can see a complete picture of the disease at one time and place. These doctors will no longer think of syphilis as a dermatitis, or osteomyelitis, or hepatitis, or endarteritis but they will conceive it as a general disease of the whole body which reveals itself to the obtuse human senses in only one manifestation.

The exhibit was a great source of encouragement with its demonstration of diagnostic certainty and therapeutic hopefulness. No longer is syphilis a spectral seizure, mysterious, elusive, implacable, vindictive, impregnable. Its presence is plainly revealed by the microscope and the test tube, and it tamely yields to mercury and salvarsan. Few other diseases may be recognized more surely or treated more successfully.

The great object of the exhibit is to inspire physicians to consider the disease as a possibility in practically all obscure conditions, especially in the early stages before irreparable destruction of tissue has occurred. Progress in the art of the practice of medicine depends on making the eyes more keen, the ears more acute, the touch more sensitive, the brain more responsive and the hand more skillful, and all the mental powers more alert so that the doctor shall recognize the trail of a disease from a few meager tracks of its entrance into the body and shall be bold to attack it before it becomes entrenched in the body. This is the inspiration of the exhibit.

SYPHILUS AND SYPHILIS

Ever so often someone refers with deep regret to the "good old days." Medical lore has its "ancient of days" as well as other fields of endeavor. We wonder what Fracaster's feelings would be today if he were suddenly precipitated into a well organized and modernly equipped clinic in which syphilitic patients were being examined and treated. We dare say that with all of his powers of keen observation he would be perplexed indeed to see the master disease in the multitude of disguises which it assumes at this time, and no doubt he would want to write more verses. In 1530, when Fracaster wrote the poem in which he so dramatically described the symptoms of a strange malady which attacked his principal character, Syphilus, a swineherd little did he dream that this killer of the race would for centuries ravage civilization and that this name over which so many victims have stuttered would draw the attention of countless scien-

tists and demand the expenditure of untold treasure in seeking its cause and cure.

Within the past fifteen years our knowledge of the pathology, diagnosis and treatment of syphilis has increased tremendously and in truth the natural history, the discovery of the spirocheta, its successful transmission to animals, the Wassermann and Kahn blood tests, and the synthesizing of the arsenicals have demonstrated the necessity for the rewriting of the bulk of our information regarding this infection. And, too, with our present methods of diagnosis and treatment, syphilis is seemingly changing in its morphology. Indeed, some syphilologists report that in their experience certain of the lesions are not only changing, but are vanishing. Naturally, someone will ask why is this and what is the answer. The why is that patients are presumably seeking medical advice and treatment early in the disease before other manifestations make

THE SYPHILIS EXHIBIT

The more one studies the Syphilis Exhibit of the Annual Meeting of the Medical Society of the State of New York, the greater seems the task accomplished by its promoters. No one could examine all the specimens that were shown or take the histories of all the patients, or read all the charts or see all the lantern slides and microscopic specimens, but every doctor who saw the exhibit got a vivid impression of the protean nature of the disease, and will recall the pos-

sibility of its existence in every obscure condition that he treats

The exhibit has a great inspirational value which is worthy of the effort put forth by the committee that had it in charge. A permanent record in this issue of the JOURNAL will carry its inspiration to those who did not see it, and will help the physicians who may wish to conduct a similar exhibit elsewhere.

GEORGE M FISHER

THE VALUE OF THE SYPHILIS EXHIBIT

The syphilis exhibit of the Medical Society of the State of New York aroused emotions of various kinds and degrees in those who studied it. At one extreme there were those who were overwhelmed by the extent of the ramifications of the disease, and felt helpless at the sight of its extensions into every organ of the body and its imitation of almost every pathological condition. They recoiled from the very immensity of the problem, and were depressed by their inability to understand it all. To these persons, syphilis is a problem that belongs to a narrow specialist, and that does not concern the general practitioner of medicine.

At the other extreme were those who took in the whole exhibit at an hour's glance, saw the obscure problems in diagnosis and treatment made clear, and gained the idea that after all syphilis is easy to understand and handle. These persons will go home and will diagnose every obscure condition as syphilis—until they see a demonstration on tuberculosis when all their diagnoses will be incipient consumption.

Between these two extremes a considerable number of thoughtful doctors hold a middle course and are neither indifferent nor over sanguine. They are awed by the numberless manifestations of the disease and will approach its diagnosis with faith and prayer—for it is a serious matter to fail to recognize syphilis when it exists, or to diagnose a case as syphilis when it is not.

The great value of the exhibit was that it revealed syphilis as an entity. A doctor is apt to be like any one of the blind men who described

an elephant as a tree, or a rope, or a snake, according to the part they happened to touch. Those doctors who have seen the manifestations of syphilis in only the skin and bones will gain a more true conception of the disease if they stand where they can see a complete picture of the disease at one time and place. These doctors will no longer think of syphilis as a dermatitis, or osteomyelitis, or hepatitis, or endarteritis but they will conceive it as a general disease of the whole body which reveals itself to the obtuse human senses in only one manifestation.

The exhibit was a great source of encouragement with its demonstration of diagnostic certainty and therapeutic hopefulness. No longer is syphilis a spectral seizure, mysterious, elusive, implacable, vindictive, impregnable. Its presence is plainly revealed by the microscope and the test tube, and it tamely yields to mercury and salvarsan. Few other diseases may be recognized more surely or treated more successfully.

The great object of the exhibit is to inspire physicians to consider the disease as a possibility in practically all obscure conditions, especially in the early stages before irreparable destruction of tissue has occurred. Progress in the art of the practice of medicine depends on making the eyes more keen, the ears more acute, the touch more sensitive, the brain more responsive and the hand more skillful, and all the mental powers more alert so that the doctor shall recognize the trail of a disease from a few meager tracks of its entrance into the body and shall be bold to attack it before it becomes entrenched in the body. This is the inspiration of the exhibit.

SYPHILUS AND SYPHILIS

Ever so often someone refers with deep regret to the "good old days." Medical lore has its "ancient of days" as well as other fields of endeavor. We wonder what Fracaster's feelings would be today if he were suddenly precipitated into a well organized and modernly equipped clinic in which syphilitic patients were being examined and treated. We dare say that with all of his powers of keen observation he would be perplexed indeed to see the master disease in the multitude of disguises which it assumes at this time, and no doubt he would want to write more verses. In 1530, when Fracaster wrote the poem in which he so dramatically described the symptoms of a strange malady which attacked his principal character, Syphilus, a swineherd, little did he dream that this killer of the race would for centuries ravage civilization and that this name over which so many victims have stuttered would draw the attention of countless scien-

tists and demand the expenditure of untold treasure in seeking its cause and cure.

Within the past fifteen years our knowledge of the pathology, diagnosis and treatment of syphilis has increased tremendously and in truth the natural history, the discovery of the spirocheta, its successful transmission to animals, the Wassermann and Kahn blood tests, and the synthetizing of the arsenicals have demonstrated the necessity for the rewriting of the bulk of our information regarding this infection. And, too, with our present methods of diagnosis and treatment, syphilis is seemingly changing in its morphology. Indeed, some syphilologists report that in their experience certain of the lesions are not only changing, but are vanishing. Naturally, someone will ask why is this and what is the answer. The why is that patients are presumably seeking medical advice and treatment early in the disease before other manifestations make

their appearance. And, too, there is no question but that the suppression of prostitution has reduced the number of exposures and consequently the number of infections has diminished. With the decrease in new cases and the mass of ma-

terial which has been printed in the last few years, the physicians have had their suspicions aroused concerning the diagnosis of syphilis and more patients are coming under treatment earlier and are receiving better care.

REST OR EXERCISE

The therapeutic value of exercise has been popularly stressed to such an exaggerated extent that physicians often have difficulty in enforcing rest upon those who need it. Scientific health journals properly emphasize the healthfulness of exercise and fresh air, and the beauty papers stress the development of muscles and the figure. School journals point out the evils of improper posture, and lay out extensive series of exercises in attempts to strengthen the muscles and infuse vigor into the body.

The people generally are fed on propaganda for exercise until they apply it for every weakened condition. Is a child round-shouldered? Then enforce a system of exercises that will result in fatigue and lassitude.

Has a child weakened leg muscles following poliomyelitis? Then make the child walk, for "everybody knows that muscles get weak and flabby when you sit around all day."

Does a young man who has a slight afternoon rise of temperature give strict heed to the doctor's advice to take absolute rest? The chances are that he will take a fifteen-minute walk "to strengthen his muscles and to get the air."

Rest and relaxation have as much therapeutic value as exercise.

Those who deal with groups of poorly nourished children realize keenly the necessity of rest, and make provision for an hour in the early afternoon during which every child shall lie down in quiet and take a complete rest—and the recuperation of vigor is in marked contrast with the fatigue which follows periods of exercise.

There is a proper balance between rest and exercise, but physicians have difficulty in making their patients see it. Rest requires a certain amount of directed effort, and people generally do not know how to relax either muscularly or nervously. The subject of rest and relaxation is worthy of serious consideration by physicians.

LOOKING BACKWARD

THIS JOURNAL TWENTY YEARS AGO

THIS JOURNAL, for June, 1906, contains a memorial of Dr. George Ryerson Fowler, delivered before the New York Academy of Medicine, May 3, 1906. Dr. Fowler was a noted Brooklyn surgeon and was one of the most active and best known workers in the State Medical Society. The JOURNAL for February, 1906, contains an account of his life, from which the following extracts are taken.

"Dr. Fowler was a man of indomitable energy. His capacity for work seemed almost without limit. Notwithstanding the vast amount of hospital and private work which he did he found time to give a large measure of his energy and thought to the general interests of the medical profession. He was always active in the affairs of his medical societies, and was always found taking a firm stand for what he believed to make for the best interests of his profession. He was one of the active movers in the amalgamation of the two great societies of the State of New York.

One of the last things to receive his attention was a movement to make accessible to all the members of the State Society the books of the library of the Medical Society of the County of Kings. He had hoped to see consummated a plan to give members of the State Society the privilege of having sent them, upon request, volumes from this library. With these objects for the general good in his mind, he went to Albany to attend the centennial meeting and reunion of the State Societies. He was stricken with appendicitis on his way to the capital city—the very disease from which he had rescued thousands—and, after an illness of ten days, in which every resource of science was exhausted, he gave up his life on February 6, 1906. A system which had been overtaxed by years of unremitting work, failed at the critical hour, and this splendid and much beloved man died because of the great labor he had done for others."

MEDICAL PROGRESS

History of Syphilis in the Far East—K Dohi, a Japanese, is publishing a serial article on this subject in the *Deutsche medizinische Wochenschrift*, from issues of which for April 9 and 16, 1926, the following is abstracted. The author, who has already published a monograph on this subject, is evidently a partisan of the modern origin of the disease, and like most writers, prefers to believe that his own people did not originate it. He is unable to find, either in Japanese or Chinese sources, any reference to a disease or epidemic which could suggest syphilis before 1500. That the latter could be masked as a form of leprosy is inconceivable, for that disease was too well known to the ancient Asiatic peoples. He makes no mention of certain Chinese writings much quoted by our historians, but has found three early writers who record what he regards as the disease in question. The first author mentions a period which coincides with our cycle 1488-1505, and toward the latter end of this period there broke out at first at Canton, later becoming pandemic, a malignant eruption. The date of the volume is 1545. The name of the disease is given as "pie chieh," which can mean syphilis. Another author who wrote in 1588 mentions the same disease as being widely diffused during the period 1506-1521. A third author who wrote at an earlier period than either—somewhere from 1520-1533—does not mention any epidemic but describes five cases of "yeung mui chang" which even today signifies syphilis. Three are probable and the other two doubtful cases. This writer knew of the venereal transmission and also that the disease is curable by mercury and a plant which corresponds to our sarsaparilla. Two contemporary Japanese authors describe an epidemic in 1512-3 that seems to have been general on the islands. One of the names given was "to kasa," which could mean syphilis. The first outbreak was in Kyoto. The author, without so stating, seems to imply that European sailors brought the disease from Portugal, but there is no evidence that any European sailors reached China or Japan at that period or anywhere near it. Portuguese reached Ceylon in 1505, Malacca 1511, Japan 1542, and China much later. The Canton epidemic must have broken out between 1500-1506, and spread to Japan by 1512. There seems to have been an outbreak of the disease over most of the maritime countries at about the same period, but the mode of diffusion is far from clear.

Nature of Metasyphilis—In an article in the *Klinsche Wochenschrift* of February 19, 1926, P. Doerr, rejecting the neurotropic views of the origin of paresis, endeavors to explain the occurrence of the latter, and of tabes by what might be called a mesodermotropic theory. We know, he says, that there are different degrees of virulence and also different degrees of tissue resistance, for we see local immunity due to allergy as well as the immunity conferred by treatment. As a general principle, all of the more highly organized tissues show much immunity, whether native or due to better circulatory, oxidative, and nutritive conditions. Conversely the connective tissues show such low resistance relatively that they have been termed the special prey of the spirochete, the tissues reacting typically to the micro-organism by the formation of a gumma. Otherwise stated, syphilis is a disease solely of the mesoderm, or at least attacks the other layers only because of the presence of connective tissue therein. Now in order to attack the highly organized nerve structures of the cortex cerebri and posterior spinal nerve roots, there must be certain changes in the pia mater brought about by the disease, as a consequence of which it loses its functional integrity and permits of permeation by the cerebrospinal fluid and interference with the nutritive conditions—oxidation, blood supply, etc.—of the nerve structures. With tissue resistance lowered the spirochete can now gain access to the nerve centers and proliferate, so that diseases develop which we call paresis and tabes. The author's views do not seem to satisfy all the possibilities, or at least he offers no explanation of the clinical distinction between ordinary lues and metasyphilis.

Familial Tabes—Guillain, Perisson, and Thevenard report one of those startling episodes which almost compel belief in the existence of neurotropic syphilis. The father, mother, and a four-year old boy all presented evidences of the tabes which was typical in the parents while the child showed only the Argyll-Robertson pupils and a positive Wassermann. Hereditary juvenile tabes is occasionally seen, but the syphilitic parents seldom present tabes themselves. Commenting on this case the authors see nothing irrational in the belief that the spirochete for one or another reason might develop a special organotropism which would result in its attacking the nervous

system only. This is not equivalent to saying that there is a special neurotropic strain which has evolved from the common race of spirochetes. The property might be casual and transitory. This sort of behavior is seen in various bacilli, notably the tubercle, typhoid, and dysentery organisms. The clinician, paying no heed to bacteriology, reached the same conclusion, even in the day of Fournier and Erb, and spoke of two separate viruses to explain syphilis and metasyphilis. There was no claim made for absolute separation, for it was conceded that the neurotropic virus was able to attack the skin under certain circumstances, although as a matter of fact this was of rare occurrence and but slight in extent. The converse was likewise seen on rare occasions, as when metasyphilitic disease followed well-marked cutaneous syphilis.—*Le Bulletin Médical*, February 17-20, 1926

Incipient General Paralysis—In the course of an inquiry recently made by Henry A. Bunker into the earliest signs of paresis, a report of which is published in the *American Journal of the Medical Sciences* for March, 1926 (CLXXI, 3) the writer found that the early symptoms, whether or not accompanied by physical signs or a positive blood Wassermann, were in almost every case disregarded or misinterpreted. In his study irritability held first rank as an early symptom, occurring as the earliest, or one of the earliest, in 42, or 57 per cent of the 74 cases. The character change whereby an individual is reduced in activity and spontaneity, loses some of his interests, tends to withdraw into himself, and is often described as having become "quiet," is likewise a common early symptom, for it occurred in 28, or 38 per cent of these cases. When this alteration in the personality of the patient was the first deviation from the normal to appear, it usually antedated the onset of frank mental symptoms by at least six months, and not infrequently by a year, a year and a half, and even longer. Loss of weight as an early manifestation ranked third numerically. It occurred—and very often early—in 22, or 30 per cent of this series. An increased tendency to sleep, somewhat more suggestive in itself than any of the foregoing symptoms, was an early manifestation in 15 cases, or 20 per cent. Speech defect, memory defect, and judgment defect have considerable diagnostic value in themselves, but they were found in this series among the early symptoms in only 11, 15, and 7 cases, respectively. Visual impairment, digestive disturbance, insomnia, fatigability, headaches, tremor, and rheumatoid pains were present as the earliest manifestations in a few cases, neurosyphilis must sometimes be considered in the differential diagnosis of these

very undistinctive symptoms. The presence of nervous and mental symptoms consistent with incipient general paralysis, if they are not otherwise clearly to be accounted for, calls at least for examination of the pupils and of the knee and ankle jerks and for a Wassermann test, and raises the question, even when the evidence from these sources is negative, of the necessity for lumbar puncture.

Rationale of the Action of Inoculation Malaria in Paresis—Donath and Heilig have made studies of the aminoacid content of the blood in artificial fever induced in both man and animals by injections of milk, trypsin, colloidal sulphur, nucleic acid, etc., and have found invariably that at the height of the fever these bodies show an increase (*Wiener klinische Wochenschrift*, March 25, 1926). Apparently we may infer that such increase is due to a general stimulation of metabolism as a result of the febrile process. Recently they tested the blood in metasyphilitic patients at the height of the fever induced by the malarial virus, but to their surprise there was no increase to be noted. It then occurred to them to test the cerebrospinal fluid and here they found the increase. Control injections of milk on the other hand produced no alteration and it was found in general that the ordinary pyretogenous substances showed no similarity of action here. This discrepancy showed that there could be more than one source for the increased aminoacid content, and the authors were forced to conclude that in paresis the increase in the spinal fluid was due to an intense focal reaction in the brain lesions of the disease. From this one may conclude that high fever alone is not sufficient to explain the cures of metasyphilis by malarial virus.

The Whittingham (W) Strain of Artificially Induced Malaria—After preliminary work with strains of quartan, malignant tertian, and simple tertian fevers in the treatment of general paralysis and tabes dorsalis, A. R. Grant and J. D. Silverston (*Journal of Tropical Medicine and Hygiene*, April 15, 1926, XXXIX, 8) concluded that the tertian was most useful for their purpose, and so the birth of the Whittingham (W) strain took place on September 8, 1922, when a general paralytic was inoculated with blood from a patient who had contracted tertian malaria in India. From this host a long chain of cases of general paralysis and tabes has been infected, using 2 c.c. of recently drawn venous blood, with the result that during nearly three and a half years the strain has been transmitted by direct subcutaneous inoculation through 60 generations, comprising over 150 cases. The incubation period calculated from the date of inoculation to the day of appearance of parasites in the peripheral blood stream, although varying occasionally between six and twenty days, was fairly

constant, averaging from ten to twelve days throughout the period. The commencement of the fever generally preceded the appearance of the parasites in the peripheral circulation by one to four days, though often the parasites and the fever coincided in the day of their appearance. The physical signs that accompany the recurring paroxysms of fever are apparently similar to those observed in mosquito malaria. Patients who are going to be improved by the treatment usually are so after five rigors, and not more than ten paroxysms seem to be justified. After a three-day course of treatment by the oral administration of hydrochloride of quinine—30 grains on each of three consecutive days—the fever quickly subsides and the parasites rapidly disappear from the blood. In some cases the fever and parasites show a tendency to disappear spontaneously. A fact of considerable interest and importance is that the prolonged sojourn of *P. vivax* in man, comprising 60 direct passages during three and a half years, has wrought no change in the pathogenicity or virulence, nor alteration in the therapeutic properties, of this organism. Again, the morphology of the parasite has not changed, differing in no way from that found in naturally infected cases. Incidentally the experience of these writers leads them to believe that malaria is not a therapeutic measure of value in nonsyphilitic psychoses.

Inoculation Malaria and Rupture of the Spleen—Bachmann, of the clinic of Professor Curschmann, states that while Wagner-Jauregg failed to see spontaneous rupture of the spleen in over 1,200 patients with metasymphilitis treated with malaria virus, cases are being reported and he has added a fifth to the series previously recorded by Alexander, Tromner, Baltzer, Herzig, and Weygandt. Thus another untoward accident from this plan of treatment has been added to a number already sufficiently formidable. In regard to the frequency of this complication in ordinary malarial patients, Davidson saw but three cases in 30,000 patients during an observation period of eight years. The accident may be overlooked at times for a diagnosis, beyond that of internal hemorrhage, is seldom made before laparotomy. It would therefore appear that the metasymphilitic patient is slightly predisposed to rupture or that inoculation malaria differs in this respect from the ordinary type. The author's patient was in excellent general condition although he had never received any antisymphilitic treatment during the eight years of his disease. The diagnosis on admission was cerebral lues with probable beginning paresis. After an observation period of 23 days to exclude the presence of febrile attacks he was placed on the malarial treatment. His first rise of temperature did not exceed 39° C (102° F), but a few hours after the second

intravenous injection he collapsed with fatal outcome, autopsy revealing rupture of the spleen without any history of a traumatic factor—*Muenchener medizinische Wochenschrift*, March 26, 1926.

Treatment of Multiple Sclerosis with Malaria Virus—Dreyfuss and Hanau, after reviewing the essays of treatment of this disease with certain vaccines and non-specific proteins which produce more or less rise of temperature, came to the conviction that in the use of pyretogenetic drugs the higher the temperature and the longer this can be maintained the better will be the result, which means that malarial virus is the remedy of choice. The authors have found this to be true in practice. They have now treated 12 patients who had the disease in the chronic progressive form without complete loss of the use of the limbs, the crippling, which was marked in all cases, being chiefly spastic in nature. The authors began the use of the virus in 1924 and the post-treatment period is necessarily brief—3 to 6 months only. Despite the smallness of the material and the short observation period the authors regard the results as striking, especially in two patients who now dispense with canes and are able to go up and down stairs. Of the original 12 patients treated 9 improved and 3 did not, and of the nine to benefit from treatment but one has shown a tendency to relapse, the remaining eight having held their gains well. After a course of malaria virus the patient returns to his former treatment, consisting of the use of some arsenical, including salvarsan, if desired. The authors do not advise the malaria treatment save in the chronic progressive case and naturally only after other measures have shown themselves inert—*Deutscher medizinische Wochenschrift*, March 5, 1926.

The Extended Use of the Whole Thickness Skin Graft—Experience has shown that the Wolfe graft, originally devised for plastic use in the repair of palpebral defects, is capable of steadily widening application. Two situations in which its use has been facilitated by the aid of new devices are described by Percival P. Cole (*The Practitioner*, April, 1926, cxvi, 4). One of these situations is in the soft parts of the face which are constantly subjected to slight movement, making difficult the maintenance of firm steady pressure. The tissue in and around the neighborhood of the lower lids is particularly prone to be affected by rodent ulcer. To meet the difficulties in excision of the ulcer, the author has devised an apparatus consisting of a broad metal forehead piece, which is lined with Stent's modeling compound, to secure a firm ac-

curately fitting bearing surface. A small piece of soft metal is cut to the shape and size of the incised area and bent to the contour of the part. When the graft has been sewn into place, the under surface of the metal plate is covered with soft Stent and gently pressed home over the area involved. Arms attached to the headpiece are so arranged that they fit snugly into a depression made on the upper surface of the little piece of metal. In this way light constant pressure is maintained with the least discomfort to the patient, and the results are practically and cosmetically reliable. By means of a perforated zinc splint, shaped for the particular case, Cole has been able to employ whole thickness skin grafts in cases of cicatricial contractions producing flexion deformities of the fingers. The zinc splint is filled with soft Stent, gently pressed over the graft and bandaged in position. The results have exceeded all anticipations and have enabled the restoration to good use of fingers recommended for amputation, because of extensive mutilations, septic infections, and burns.

Rope Grafts—After describing the Gillies method of employing the tube graft, Frank H. Lahey (*Boston Medical and Surgical Journal*, January 7, 1926, cxciv, 1) calls attention to a few factors which his experience has taught him go to bring about success or failure. It is necessary to make the two parallel incisions, which mark out the flap, sufficiently far apart so that the strip will be wide enough to permit of connecting it into a tube and yet not so to constrict it that there will be a definite blanching of the segment when the approximating sutures are tied. It is a distinct advantage to have a moderate amount of subcutaneous fat, so that when the tube is constructed its center is completely filled with adipose tissue and contains no dead space or canal, insuring thus no pocket for the accumulation of serum, and also walls of sufficient thickness to provide an adequate blood supply. Careful measurements should be made as to the distance between the point into which the graft is to be inserted and the point which is to serve as the base of the pedicle, in order to avoid tension which may shut off the circulation and result in necrosis and loss of the transplant. To test the vascularity of the graft when it is ready for transfer, a string is tied around the end to be transferred and, after stripping the tube until it is pale, a second ligature is tied around the base. At the end of a minute or two the ligature at the base is removed, and the degree of flushing and the rapidity with which it descends the graft is noted. If a good red color appears and rapidly runs down the tube, it may be transferred without fear of any lack of blood supply. If the tube is restored to its bed after being cut away from the transplanted flap, it must be split along its

line of suture, its edges undercut and the central cord of subcutaneous fat rimmed out. The edges of the wound into which the flap is to be returned must be sharply undercut to ensure good approximation.

Head Colds—A cold in the head ranks with seasickness as one of the most studied and least understood, in a practical therapeutic sense at least, of all human maladies. We have slowly awakened to the fact, and are even more slowly beginning to act upon the conviction, that colds are infectious and potentially very serious diseases, and any article on the subject written by one in authority is read with interest in the hope, not always realized, that it will shed new light in a very dark etiological and therapeutic corner. In a recent communication of some interest, published in the *Muenchener medizinische Wochenschrift* of April 20, 1926, Hans Much, a German pathologist, places colds in a group of infections communicated from pharynx to pharynx, which group has a number of members. Invasion of the nose he regards evidently as secondary. The factors which produce a common cold he holds to be the same as those behind most infections. There is an exciting organism but the mere fact that it can transmit an infection from person to person is not enough to explain epidemics and endemics. There is the constitution of the patient to consider—the relative susceptibility and immunity—in connection with the relative virulence or innocuousness of the germ. There is a third factor, the unknown principle which may either lower individual resistance or stimulate the activity of the exciter. Until we know more about this we must associate it with the weather, the changes of which somehow affect living creatures in general, giving rise to a kind of recurring periodicity. The popular name for this disease—a cold—suggests the power of the weather to lower individual resistance. The bacterial factor may at present be overvalued. Much thinks, in support of which he recounts an experience with epidemic cerebrospinal meningitis in which he was officially active. The outbreak was combated in the usual manner, by isolation of patients and examination and isolation of healthy carriers. Toward the end of the epidemic, just when the meningococcus should have been disappearing from the throats of exposed healthy subjects the number of the latter whose throat swabs were positive, was constantly increasing, yet no new cases developed. In other words, the cocci had completely lost their virulence. The author is very properly and justly opposed to testing virulence on guinea pigs, for he has never seen a true human infection which could be reproduced literally in an animal.

THE DAILY PRESS

THE PROBLEM OF THE FEEBLE MINDED

The *Herald-Tribune* of June third carries an editorial comment on the meeting of the American Association for the Study of the Feeble Minded recently held in Toronto. The newspaper says that the control of the feeble minded is the greatest public health problem in the world. It quotes Dr F E Williams, Medical Director of the National Committee for Mental Hygiene as saying that more than 75,000 new mental patients are now appearing each year at the hospitals and insane asylums. The editorial continues, "If the chief asset of a nation is its citizenry, these figures raise a disquieting suspicion that far too many of our population are going mad."

"It is unwise, however, to jump too hastily at this pessimistic conclusion. There is no denying the figures. The number of registered insane is really increasing. This is true both in the United States and in the world as a whole. But this may not mean an actual increase of insanity or any real deterioration of the average American mind. The increases may be due merely to better diagnosis. Fifty years ago an individual had to be rather violently insane before he was called so, before the restraints of the asylum were invoked. Every community had its half wits or three-quarter wits. These were tolerated, helped, written down in the census returns as normal. Asylums were dreaded. The subnormal child was kept at home, concealed by the family as a disgrace. The apparent increase in the numbers of idiots and insane is probably an increase of frankness rather than an increase in actual abnormality."

The editorial goes on to say, "Nevertheless, the existence of any feeble mindedness at all marks one of the failures of medical science. It is prob-

ably no more a necessary infliction of society than is smallpox. Smallpox has been conquered, mental defects may be. The trouble at present is that we know so little of the causes of these defects. There is evidence that mental weakness is frequently inherited. One of the speakers at Toronto will be Dr Charles B Davenport, of the department of eugenics of the Carnegie Institution, who will discuss this evidence and what to do about it. Somehow the percentage of mental defectives must be reduced. It is the job of scientists like Dr Davenport to show us how."

This is only half true. There is much more than "evidence" that mental weakness is "frequently" inherited. Medical science demonstrates that heredity is by far the principal cause of feeble mindedness.

The remedy is obvious—prevent propagation by the feeble minded. But at present this is almost entirely a social and not a medical problem. Medical men are willing to do their part in the sterilization of habitual criminals and the feeble minded and legislators are willing to legalize the performance of the necessary operations, and the patients themselves are willing and even anxious to have the operations done—but sentimentalists object with such vehemence that little or nothing is done.

Such compulsory measures are not permitted, education is the only weapon available. But young persons believe that beauty and attractiveness and perfection of the body indicate similar traits of the mind, and the moron flapper continues to catch the unsophisticated honor students.

After all it is reassuring that the stern law of nature is still operative in the elimination of the unfit and the survival of the fittest, and that the race is continually evolving upward in mentality.

THE PROBLEM OF ACCIDENTS

The popular conception of the word accident is that it means something that just happens and cannot be prevented, yet employers of labor consider them to be preventable. No longer is an ignorant workman compelled to take the chances of being disabled for life from causes over which no one is supposed to have control. The new conception is that all so-called accidents may be preventable—that is, they are due to causes which can be foreseen and can be controlled.

The *New York Sun* of June first contains a news item and an editorial on the report of the

United States Steel Corporation regarding the accidents in the plants. The popular belief naturally is that the steel mills with their ponderous machinery, heavy metal, the heat and dust, should be peculiarly likely to have numerous accidents that are peculiar to the industry, yet ninety per cent of the accidents were due to causes which are common to all industries and only ten per cent were due to the special hazards of the industry. The editorial says "Contrary to a somewhat general impression, most accidents in such industrial plants are not due to hazards peculiar to the

industry or to its machinery. Charles L. Close, manager of the corporation's Bureau of Safety, Sanitation and Welfare, has found that hot metal, flue dust and flame have been responsible for less than 5 per cent of the total and that only 4.9 per cent were due to machinery. Nearly half of the whole number of accidents have been due to hand labor where safety cannot be assured by mechanical devices or appliances."

The law recognizes that "accidents" are preventable and the Steel Corporation recognizes its justice by spending immense amounts of money to eliminate them, and the results are well worth while. The editorial says:

"A review of twenty years of organized effort to prevent accidents in the plants of the United States Steel Corporation discloses that 46,000 persons have been saved from death or serious injury and 322,000 others have been saved from less serious accidents which would, however, have disabled them. These totals are reached by calculating on a percentage basis, taking into consideration the high number of accidents reported annually before Judge Gary authorized the accident prevention movement and those which have happened each year since.

"The figures show a reduction of more than 60 per cent in serious accidents and of more than 80 per cent in less serious ones. Secretary Davis of the United States Department of Labor in a letter to Judge Gary observed that in a group of plants, composed largely of the Steel Corporation's subsidiaries, the accident frequency ratio has dropped from 60.3 for each million hours of exposure in 1913 to 10.2 for each million hours in 1924, a reduction of 83 per cent.

"Here remedial efforts must mainly take the form of education for the individual worker. This has not been possible without considerable expense. A report prepared by Mr. Close's bureau covering the last fourteen years shows that the corporation has spent \$158,000,000 in that period for safety, sanitation and welfare. Direct accident prevention accounts for only \$15,700,000 of the total, the rest going for pensions, relief, sanitation, playgrounds, schools, clubs, gardens, visiting nurses and the like. Arthur Williams, president of the American Museum of Safety, declares this the most astounding record of accomplishment in accident prevention and health promotion he has seen in the fifteen years of his association with the safety movement.

"Aside from all humanitarian consideration, Judge Gary has figured on a dollar and cents basis that such expenditures bring handsome returns. He estimates that in ten years the Steel Corporation paid \$9,763,063 in accident prevention work and that the money saving resulting therefrom was \$14,609,920.

"With such evidence on record it is indeed true, as Mr. Williams says, that there is no longer excuse for the failure of any industry to give the utmost attention to organized accident prevention. It is no longer a mere matter of shouting 'Safety First!' but a question now of impressing on the minds of everybody that 'Safety Pays'."

The prevention of accidents is largely a medical problem, for inattention due to fatigue is one of their greatest causes. The psychological effect of lighting, ventilation, eye strain, and other working conditions also come under the control of expert medical men.

The reduction in the number of accidents and the improved morale and health of workmen generally are great items to the credit of the medical profession which are recognized by the daily press.

Yet the prevention of accidents is not entirely or even principally a medical problem. Why do people get impatient and take chances? That is a question for psychologists and business people to answer.

Why do owners disregard the plain warnings of ramshackle buildings that fall down, and of worn machinery that breaks down and injures workmen? The solution of that problem is largely the work of preachers and Sunday School teachers.

Why do people take chances at street crossings and show an utter disregard of rules and regulations? The work of the school teachers in training the people to obey is a great factor in preventing accidents.

Even fatigue, one of the greatest of causes of accidents cannot be prevented by medical means. Late hours at dances and revels will be followed by fatigue the next day in spite of the best efforts of sanitarians.

The managers of mills and factories and transportation lines may provide means of safety, but it almost seems that the people go out of their way to invite accidents.

DEATHS

HOPE, GEORGE BEVAN, New York City, Bellevue Medical College, 1875, Member State Society, Alumni Association Bellevue Hospital, Surgeon Metropolitan Throat Hospital, Consulting Physician Harlem Eye, Ear and Throat Infirmary Died April 18, 1926

HOPKINS, HENRY REED, Buffalo, University of Buffalo, 1867, Member State Society, Buffalo Academy of Medicine, Consulting Physician General Hospital Died March 6, 1926

HOWK, HORACE JOHN, Mount McGregor, University of Michigan, 1907, Fellow American Medical Association, Fellow American College of Physicians, National Tuberculosis Association, American Public Health Association, Member State Society Died April 8, 1926

JOYCE, THOMAS URQUHART, Brooklyn, Long Island College Hospital, 1881, Member State Society Died April 1, 1926

KAHN, MAX, New York City, Cornell Medical College, 1910, Fellow American Medical Association, New York Academy of Medicine, Member State Society, Visiting Physician and Director of Laboratories Beth Israel Hospital, Chief, Department of Metabolism Israel Zion Hospital Died April 9, 1926

KANDT, HARTWIG, Brooklyn, Long Island College Hospital, 1906, Fellow American Medical Association, Fellow American College of Physicians, National Tuberculosis Association, Brooklyn Pathological Society, Member State Society, Attending Physician Methodist Episcopal Hospital, Consulting Physician Wyckoff Heights Hospital Died March 25, 1926

KATZENBACH, WILLIAM HENRY, New York City, Bellevue Medical College, 1871, Fellow American Medical Association, New York Academy of Medicine, Alumni Association Bellevue Hospital, Member State Society, Attending Physician Polyclinic Hospital Died March 19, 1926

KENE, JOSEPH ALPHONSE, Brooklyn, New York University, 1878, Fellow American Medical Association, Brooklyn Neurological Society, Member State Society, Attending Physician St. Peter's Hospital, Consulting Physician St. Anthony's Hospital Died March 11, 1926

LINELIA, HARLAN EDWARD, Brooklyn, Baltimore Medical College, 1907, Member State Society Died March 9, 1926

MCCLELLAND, LEFFERTS AUGUSTUS, Brooklyn, Long Island College Hospital, 1885, Fellow American Medical Association, Fellow American College of Surgeons, American Laryngological, Rhinological and Otological Society, American Academy of Ophthalmology and Oto-Laryngology, Brooklyn Pathological Society, Member State Society, Otologist and Laryngologist Broad Street, Community, Mercy, Hempstead and South Side, Bay Shore, Hospitals, Otologist Coney Island, Rockaway Beach and Kingston Avenue Hospitals Died April 12, 1926

MCGUIRE, CONSTANTINE F, New York City, Bellevue Medical College, 1882, Member State Society Died April 15, 1926

MERRILL, CYRUS STRONG, Albany, College of Physicians and Surgeons of New York, 1871, Fellow American Ophthalmological Society, American Otological Society, Member State Society, Ophthalmological and Otological Surgeon Albany and Child's Hospitals Died March 17, 1926

MOFFAT, HENRY, Yonkers, College of Physicians and Surgeons of New York, 1881, Fellow American Medical Association, Fellow American College of Surgeons, New York Academy of Medicine, Member State Society, Alumni Association St. Luke's Hospital, Consulting Surgeon St. Joseph's, Tarrytown and Ossining Hospitals Died March 25, 1926

MORGAN, THOMAS HENRY, New York City, Trinity, Toronto, 1897, Fellow American Medical Association, Fellow American College of Surgeons, Member State Society, Surgeon St. Elizabeth's Hospital, Assistant Gynecologist Polyclinic Hospital Died April 9, 1926

POLON, ALBERT, New York City, Cornell Medical College, 1910, Fellow American Medical Association, American Psychoanalytic Association, New York Psychoanalytic Association, Member State Society, Attending Neurologist Vanderbilt Clinic Died March 15, 1926

RICHE, PAUL, New York City, Long Island College Hospital, 1907, Fellow American Medical Association, Member State Society Died March 23, 1926

ROOF, STEPHEN WHITE, New York City, University and Bellevue Medical College, 1906, Fellow American Medical Association, Member State Society, Junior Surgeon Manhattan Eye, Ear and Throat Hospital, Consulting Otologist and Laryngologist Nyack Hospital Died March 13, 1926

industry or to its machinery Charles L. Close, manager of the corporation's Bureau of Safety, Sanitation and Welfare, has found that hot metal, flue dust and flame have been responsible for less than 5 per cent of the total and that only 4.9 per cent were due to machinery. Nearly half of the whole number of accidents have been due to hand labor where safety cannot be assured by mechanical devices or appliances."

The law recognizes that "accidents" are preventable and the Steel Corporation recognizes its justice by spending immense amounts of money to eliminate them, and the results are well worth while. The editorial says:

"A review of twenty years of organized effort to prevent accidents in the plants of the United States Steel Corporation discloses that 46,000 persons have been saved from death or serious injury and 322,000 others have been saved from less serious accidents which would, however, have disabled them. These totals are reached by calculating on a percentage basis, taking into consideration the high number of accidents reported annually before Judge Gary authorized the accident prevention movement and those which have happened each year since.

"The figures show a reduction of more than 60 per cent in serious accidents and of more than 80 per cent in less serious ones. Secretary Davis of the United States Department of Labor in a letter to Judge Gary observed that in a group of plants, composed largely of the Steel Corporation's subsidiaries, the accident frequency ratio has dropped from 60.3 for each million hours of exposure in 1913 to 10.2 for each million hours in 1924, a reduction of 83 per cent.

"Here remedial efforts must mainly take the form of education for the individual worker. This has not been possible without considerable expense. A report prepared by Mr. Close's bureau covering the last fourteen years shows that the corporation has spent \$158,000,000 in that period for safety, sanitation and welfare. Direct accident prevention accounts for only \$15,700,000 of the total, the rest going for pensions, relief, sanitation, playgrounds, schools, clubs, gardens, visiting nurses and the like. Arthur Williams, president of the American Museum of Safety, declares this the most astounding record of accomplishment in accident prevention and health promotion he has seen in the fifteen years of his association with the safety movement.

"Aside from all humanitarian consideration, Judge Gary has figured on a dollar and cents basis that such expenditures bring handsome returns. He estimates that in ten years the Steel Corporation paid \$9,763,063 in accident prevention work and that the money saving resulting therefrom was \$14,609,920.

"With such evidence on record it is indeed true, as Mr. Williams says, that there is no longer excuse for the failure of any industry to give the utmost attention to organized accident prevention. It is no longer a mere matter of shouting 'Safety First!' but a question now of impressing on the minds of everybody that 'Safety Pays!'"

The prevention of accidents is largely a medical problem, for inattention due to fatigue is one of their greatest causes. The psychological effect of lighting, ventilation, eye strain, and other working conditions also come under the control of expert medical men.

The reduction in the number of accidents and the improved morale and health of workmen generally are great items to the credit of the medical profession which are recognized by the daily press.

Yet the prevention of accidents is not entirely or even principally a medical problem. Why do people get impatient and take chances? That is a question for psychologists and business people to answer.

Why do owners disregard the plain warnings of ramshackle buildings that fall down, and of worn machinery that breaks down and injures workmen? The solution of that problem is largely the work of preachers and Sunday School teachers.

Why do people take chances at street crossings and show an utter disregard of rules and regulations? The work of the school teachers in training the people to obey is a great factor in preventing accidents.

Even fatigue, one of the greatest of causes of accidents cannot be prevented by medical means. Late hours at dances and revels will be followed by fatigue the next day in spite of the best efforts of sanitarians.

The managers of mills and factories and transportation lines may provide means of safety, but it almost seems that the people go out of their way to invite accidents.

into the study of the science of neurology, we are given an account of the man himself, his personality, character and a brief outline of his career. Dr Sir John Hutchinson has contributed "Recollections of a Lifelong Friendship" to this volume and Dr Mercier has also donated his "Recollections", to both of these gentlemen do we owe the pleasure of becoming acquainted with a remarkable man, blessed with a sense of humor, whose method in every task was thoroughness and getting to the very root of any possible problem. The chapters by Dr Jackson are priceless in the study of neurology. Many valuable discoveries in this science are the result of the tireless and profound efforts in the lifework of a real genius in his particular world.

F. C. E.

PLASTIC SURGERY OF THE NOSE. By J. EASTMAN SHEEHAN, M.D. F.A.C.S., Associate Surgeon and Lecturer International Clinic of Otorhinolaryngology and Facio-Maxillary Surgery Paris, Plastic Surgeon and Chief of Nose and Throat Clinic, New York Post-Graduate Medical School and Hospital, foreword by JOHN F. ERDMANN, M.D., F.A.C.S., Professor of Surgery, New York Post-Graduate Medical School and Hospital. Paul B. Hoeber, Inc., New York, 1925. Price, \$10.00.

This volume covers the plastic operations on the nose in a very concise manner. The book is particularly valuable because of its numerous and well planned illustrations and the explicit manner in which the author outlines the various operations for deformities of the nose.

PEDRO PLATOU

ENERGETIQUE CLINIQUE PHYSIOPATHOLOGIE—THERAPEUTIQUE. A. MARTINET. *Le Sympathique, Le Vague, Les Reflexes, De La Vie Organo-Vegetative.* Publie Par Les Sons Du Dr Martingay. Masson et C. Editeurs, Libraires De L'Academie De Medecine, 120 Boulevard Saint-Germain, Paris, 1925.

The author has given us a very comprehensive treatise on the anatomy physiology and pathological physiology of the autonomic nervous system. The discussions of Raynaud's syndrome and of angina pectoris are interesting from this point of view. The question of sympathectomy is well discussed in these two conditions.

Basedow's disease is analysed from the point of view of the vegetative nervous system and found to be made up of phenomena attributed to disturbances largely of the sympathetic system but also of the vagus and endocrine systems as well, in other words an autonomic and endocrine imbalance.

Vagotonia is thoroughly discussed and under it a syndrome called "hypophyse" is described. The distinguishing feature of this is a low differential blood pressure in relation to a high viscosity of the blood. Clinically, the picture seems to be—small pulse tendency to cyanosis, cold extremities, congestion of the liver, hemorrhoids, varicose veins, oliguria and muscular dystrophy.

There are good chapters on the pharmacology of the vegetative nervous system and the treatment of its disorders.

Throughout the work however, there is a tendency to divide disease entities up into multitudes of special syndromes whose descriptions are meticulous but confusing to the American reader.

The last part of the volume is devoted to a highly theoretical and technical discussion of general organic energy in the human body and its adaptation to changes in environment. An attempt is made to understand the integral energy of life.

EDWIN P. MAYNARD JR.

HEXOSAMINES AND MUCOPROTEINS. By P. A. LEVENE. The Rockefeller Institute for Medical Research, New York. Longmans, Green and Co., 1925. Price, \$3.75.

The author of this monograph has gathered under one cover the observations of his own explorations and of others on a difficult frontier of bio-chemistry.

The subject of hexosamines is introduced by a short chapter on the simple sugars with especial emphasis on their isomeric modifications. The theoretical discussion of the hexosamines and their derivatives is followed by practical methods for their preparation. A similar scheme is used in the treatment of the chondroitin and mucic acid sulphuric acids, also for the mucoproteins and glucosidoproteins. An historical synopsis showing the difficulties encountered by earlier workers on these compounds is an interesting addition. A bibliography is also included.

It is essentially a book for the chemist who concerns himself with searching out the structure of these complex substances.

A. G.

DEVELOPMENT OF OUR KNOWLEDGE OF TUBERCULOSIS. By LAWRENCE F. FLICK, M.D., LL.D., Chairman of the Committee on International Congress on Tuberculosis in Washington, 1908, Ex-President International Anti-tuberculosis Association. 739 Pine Street, Phila., Pa., 1925. Price, \$7.50.

In this remarkable work Dr. Flick has written a complete history of the development of our knowledge of tuberculosis, from the very earliest ages—even pre-Grecian—down through all the centuries to and including the work of our own Theobald Smith on the bovine bacillus. In performing this arduous task the author has spared no details and yet has managed to achieve a most readable treatise, making all who are interested in so vast and so vital a subject very much his debtors. It is a reference work of such value that no well informed medical mind can afford to be without it. We congratulate the author on the success of his labors which must have been stupendous and especially do we congratulate the profession in now having at hand so invaluable a mine of information.

FOSTER MURRAY

PRACTICAL PHYSIOLOGICAL CHEMISTRY. By SYDNEY W. COLE. M.A. Sixth Edition. Octavo of 405 pages. Baltimore: Williams and Wilkins Company, 1920. Cloth, \$4.00.

This volume should prove a useful laboratory manual for students of physiological chemistry. In addition to definitely worded directions for the preparation of various bio-chemical substances the book contains sufficient chemical information of a general character to make it of value as a text book. Profuse illustrations and logical arrangement of subject matter are conspicuous features of this (sixth) edition. It seems strange to find no mention of insulin in a book of this character but the volume was published some years before Banting's discovery.

FRANK E. MALLON

POST-MORTEM APPEARANCES. By JOAN M. ROSS, M.B., B.S. M.R.C.S., L.R.C.P. 12mo of 216 pages. New York, Oxford University Press, 1925. Cloth, \$2.50 (Oxford Medical Publications).

This little book of about two hundred pages presents in a concise and brief manner the anatomical findings as shown at death from various poisons and the common diseases. Each disease is described separately first mentioning the external appearance of the body at death, then the internal appearance. In describing the latter, the different systems such as the circulatory, respiratory, digestive, renal, nervous, and skeletal systems are mentioned in so far as they contribute to the cause of death, or are a part of the particular disease.

The book is of value in that it describes the chief lesions in a condensed form.

E. H. NIDISH

BOOK REVIEWS

THE INTERNAL SECRETIONS OF THE SEX GLANDS The Problem of the "Puberty Gland" By ALEXANDER LIPSCHÜTZ, M.D. With a Preface by F. H. A. MARSHALL, F.R.S. Octavo of 513 pages, with 142 illustrations. Baltimore, Williams and Wilkins Company, 1924. Cloth, \$6.00.

Dr Lipschütz has written what will be considered a classic on the subject for a good many years to come. He presents the present-day knowledge of the sex glands from every view point that has been studied and discusses each problem in detail.

He restricts the term of endocrine gland to those glands which as far as we know, have no other function than that of the secretion of specific substances which enter into the blood and which influence the other organs in a specific manner, i.e., organs secreting chemically specific hormones.

According to him, there can be no development of sex characters without all the other organs of internal secretion participating, all of these glands are influenced by the former. He tends towards the idea that while the generative cells are not concerned directly with the production of a hormone, still the process of spermatogenesis is connected with the transformation of the interstitial cells into an active endocrine apparatus.

He does not think that the seminal vesicles, prostate gland or the genital passages are concerned with the elaboration of a hormone although it is likely that the secretion of these parts are very important.

There are very interesting chapters discussing the isolation of the sex hormone, hermaphroditism, eunuchoidism, sexual precocity, rejuvenation and sex determination.

This is one of the most valuable books written on the internal secretions of the sex glands.

M. B. GORDON

MIDDLE AGE AND OLD AGE. By LEONARD WILLIAMS, M.D. Octavo of 296 pages. London, Humphrey Milford, New York, Oxford University Press, 1925. Cloth, \$3.25 (Oxford Medical Publications).

This book contains the author's opinions upon the mode of life after one has passed his youth. Essentially the book is advisory and the methods of saving one's energy in the processes of living are described. Warning symptoms from the various systems of the body are mentioned and commented upon. As a source of new information, the book is a disappointment. Much ground has been covered and the author has given much of himself and his experience in completing the work. As an adjunct to the treatment of diseases of middle life and old age, it may be helpful to the reader.

HENRY M. MOSES

AIDS TO SURGICAL DIAGNOSIS By CECIL P. G. WAKELEY, F.R.C.S., Assistant Surgeon, King's College Hospital. William Wood & Co., New York, 1925. Price, \$1.50.

This is a very short and concise volume which contains a few of the more essential points relative to the diagnosis and differential diagnosis of the more common surgical conditions. The data is very well assimilated and it should be a very useful volume to a busy practitioner of surgery. Mr Wakeley makes his own criticism in the title and preface of the book.

A few of the more difficult surgical diagnoses of comparatively rare conditions should be substituted for some of those mentioned in the book. As for instance,

nothing is said relative to the differential diagnosis of torsion of the spermatic cord, but space is allotted to a comparatively rare condition as a tubulo-dermoid cyst of the floor of the mouth.

HERBERT I. WIKLE

A TEXT-BOOK OF MEDICAL DIAGNOSIS By JAMES M. ANDERS, M.D., Ph.D., LL.D., and L. NAPOLEON BOSTON, A.M., M.D. Third Edition, entirely reset. Octavo of 1,422 pages, with 555 illustrations. Philadelphia and London, W. B. Saunders Company, 1925. Cloth, \$12.00.

This third edition, with its 1,366 pages of text and splendid index of 56 pages, will prove a highly valuable book to the general practitioner. Its numerous illustrations, excellent discussion of methods of examination and special diagnostic technique, splendid table of differential diagnosis, comprehensiveness, and simple, terse style make it a book to be highly recommended.

M. A. R.

CLINICAL THERAPEUTICS By ALFRED MARTINET, M.D., Paris, France. Authorized English Translation from the Second Revised and Enlarged Edition. By LOUIS T. DEM SAJOURS, M.D., Philadelphia. Complete in two royal octavo volumes. Vol. I—Therapeutic Agents and Procedures. Vol. II—Treatment of Symptoms and Diseases. F. A. Davis Company, Publishers, Philadelphia, 1925. Price, \$16.00 net.

This work is a complement to an earlier one entitled "Clinical Diagnosis," of which four French and two American editions have already appeared.

There are two volumes with the subject matter divided as follows: Volume I, Part I—Therapeutic Agents, drug and dietetic therapy, physiotherapeutic and psychotherapeutic agencies are very completely described. Part II—Therapeutic procedures describes technical procedures from simple cupping to pericardial puncture and neurolytic injections. Volumes II, Part III is entitled "Treatment of Symptoms" and contains rather comprehensive symptomatic treatment for practically any symptom, with, in many instances, a tabular synopsis of the treatment of individual symptoms, by physical and pharmacologic measures. Part IV deals with the treatment of diseases. In this section is presented a very valuable account of up to date clinical therapeutics. Wherever possible the treatment is based on the etiologic, physiopathologic, anatomic and symptomatic diagnoses.

Any further detailed description of this work is impractical here, containing as it does no high lights but a wealth of therapeutic information. Symptomatic treatment is not stressed but is considered in its relation to the disease entity.

It should be of great value for reference.

JOSEPH G. TERRENCE

NEUROLOGICAL FRAGMENTS By J. HUGHLINGS JACKSON, M.D., F.R.S., F.R.C.P. With Biographical Memoir by James Taylor, M.D., F.R.C.P., and including the "Recollections" of the late Sir Jonathan Hutchinson and the late Dr. Charles Mercier. Octavo of 277 pages. London, Humphrey Milford, New York, Oxford University Press, 1925. Cloth, \$3.75 (Oxford Medical Publications).

In addition to a compilation of lectures, remarks and interesting cases of nervous diseases by Dr. Jackson, the neurologist, which proves to what extent he entered

NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL 26, No 13

NEW YORK, N Y

JULY 1, 1926

THE COUNTY HEALTH DEPARTMENT OF CATTARAUGUS COUNTY, NEW YORK AN EDITORIAL DESCRIPTION OF THE RURAL HEALTH DEMONSTRATION

THE annual meeting of the State and local committees on Tuberculosis and Public Health of the State Charities Aid Association, held on June 1, 2, and 3, 1926, was an event to which a whole number of this Journal may well be devoted. The importance of the meeting is two-fold

1 It was the annual meeting of the representative lay health organizations of the State and its counties, and was analogous to the annual meeting of the Medical Society of the State of New York and the Annual Conference of the officials of the Departments of Health of the State and its cities, villages, and towns—these three groups of organizations being the trinity of organized forces engaged in the conservation and promotion of the health of the people

2 The subject of the meeting was the work of the Health Department of Cattaraugus County—the only County Department of Health in New York State.

While the meeting was conducted by the State Charities Aid Association, the officials of the Departments of Health of the State and County, and the representatives of the Medical Society of the State of New York also took an active part in the proceedings

The County Department of Health The Department of Health of Cattaraugus County was organized on January 1, 1923, under the provisions of the Public Health Law, Chapter 636 of the laws of 1923 and Chapter 499 of the laws of 1926, which added Section 20-b. This section permits the Board of Supervisors of any county to establish a general health district of any part or all of a county except its cities, and may include the cities that wish to enter it. The district of Cattaraugus County takes in the entire county including the cities

The county health work is also operated under three other sections

1 Chapter 638 of the laws of 1923 adding Section 20-c to the Public Health Law permitting Boards of Supervisors to establish county laboratories

2 Chapter 194 of the laws of 1924, adding Section 577-b to the Education Law permitting Boards of Education to establish school hygiene districts

3 Chapter 278 of the laws of 1924, and Chapter 367 of the laws of 1926, amending Section 19 of the Public Health Law providing for state aid of local health projects

The County Health Department, acting under these four laws, leads in all the health work of the County. However, the local health officers of the cities, villages, and towns continue in office and perform all the duties with which they were charged previous to the establishment of the County Health Department, the only difference being that they are under the supervision of the County Health Officer

In addition, the County Department of Health acts in close cooperation with the County lay health organization—the Committee on Tuberculosis and Public Health of the State Charities Aid Association

Thus, all the public health agencies of Cattaraugus County, except the Medical Society of the County of Cattaraugus, are largely centered in the County Department of Health

Finances The Cost of the County Health Department is met from four sources

1 Appropriations of public funds by the County Board of Supervisors

2 The State of New York.

3 The Trustees of the Milbank Fund

4 The sale of Tuberculosis Christmas Seals

It is obviously impossible for the County and State to appropriate money for the support of work conducted by lay organizations, and so financial assistance from unofficial sources is essential in conducting the work

Scope of the Work The object of the unified and centralized Department of Health of the County is to demonstrate the value of comprehensive public health work along all modern lines, extending to every part of the County. The work which is done is similar to that done in New York, Detroit, and other up-to-date cities

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

THE COUNTY HEALTH DEPARTMENT OF CATTARAUGUS COUNTY, NEW YORK AN EDITORIAL DESCRIPTION OF THE RURAL HEALTH DEMONSTRATION

THE annual meeting of the State and local committees on Tuberculosis and Public Health of the State Charities Aid Association, held on June 1, 2, and 3, 1926, was an event to which a whole number of this Journal may well be devoted. The importance of the meeting is two-fold.

1 It was the annual meeting of the representative lay health organizations of the State and its counties, and was analogous to the annual meeting of the Medical Society of the State of New York and the Annual Conference of the officials of the Departments of Health of the State and its cities, villages and towns—these three groups of organizations being the trinity of organized forces engaged in the conservation and promotion of the health of the people.

2 The subject of the meeting was the work of the Health Department of Cattaraugus County—the only County Department of Health in New York State.

While the meeting was conducted by the State Charities Aid Association the officials of the Departments of Health of the State and County, and the representatives of the Medical Society of the State of New York also took an active part in the proceedings.

The County Department of Health. The Department of Health of Cattaraugus County was organized on January 1, 1923, under the provisions of the Public Health Law, Chapter 636 of the laws of 1923 and Chapter 499 of the laws of 1926, which added Section 20-b. This section permits the Board of Supervisors of any county to establish a general health district of any part or all of a county except its cities, and may include the cities that wish to enter it. The district of Cattaraugus County takes in the entire county including the cities.

The county health work is also operated under three other sections.

1 Chapter 638 of the laws of 1923, adding Section 20-c to the Public Health Law, permitting Boards of Supervisors to establish county laboratories.

2 Chapter 194 of the laws of 1924, adding Section 577-b to the Education Law permitting Boards of Education to establish school hygiene districts.

3 Chapter 278 of the laws of 1924, and Chapter 367 of the laws of 1926, amending Section 19 of the Public Health Law providing for state aid of local health projects.

The County Health Department, acting under these four laws, leads in all the health work of the County. However, the local health officers of the cities, villages, and towns continue in office and perform all the duties with which they were charged previous to the establishment of the County Health Department, the only difference being that they are under the supervision of the County Health Officer.

In addition, the County Department of Health acts in close cooperation with the County lay health organization—the Committee on Tuberculosis and Public Health of the State Charities Aid Association.

Thus, all the public health agencies of Cattaraugus County, except the Medical Society of the County of Cattaraugus, are largely centered in the County Department of Health.

Finances. The Cost of the County Health Department is met from four sources.

1 Appropriations of public funds by the County Board of Supervisors.

2 The State of New York.

3 The Trustees of the Milbank Fund.

4 The sale of Tuberculosis Christmas Seals.

It is obviously impossible for the County and State to appropriate money for the support of work conducted by lay organizations, and so financial assistance from unofficial sources is essential in conducting the work.

Scope of the Work. The object of the unified and centralized Department of Health of the County is to demonstrate the value of comprehensive public health work along all modern lines, extending to every part of the County. The work which is done is similar to that done in New York, Detroit, and other up-to-date cities.

The promoters of the County work believed that the best kinds of public health work that is done in cities could be done in rural communities, if it were organized on a county-wide plan. The work was frankly a *demonstration*, and its promoters had full faith in its success. Well-known experts in all lines of public health work were consulted, and they were largely responsible for the plans which were adopted. There was a possible source of misunderstanding in the development of plans from outside the County, but the advantages of the plans were that proven methods could be put into operation at once, with the expectation that they would be modified according to conditions as they arise. As a matter of fact, the plans and methods of work have been somewhat modified during the three and a half years of the demonstration.

Division of Work The work of the local health officers, 23 in number, is continued as in other counties. However, they have been encouraged, and their duties have been modified, coordinated and defined, and their field of usefulness increased by the cooperation and assistance of the County Department of Health.

The work of the County Department of Health is conducted under seven bureaus as follows:

- 1 Health Education
- 2 Public Health Nursing
- 3 Tuberculosis
- 4 Communicable Diseases
- 5 Maternity, Infancy, and Child Hygiene
- 6 Laboratories
- 7 Sanitation

There was also appointed a director of school hygiene who supervised and directed the work of examining the school children and correcting their defects. Although this work is fully coordinated with that of the County Health Department, and is administered by it, yet it is not officially a part of its activities.

The personnel at the outset was small and consisted of the following:

- 1 A County Health Officer
- 2 A Public Health Nurse
- 3 A Clerk

The present personnel is as follows:

- 4 Physicians
- 12 Nurses
- 1 Statistician
- 3 Technicians in the Laboratory
- 7 Clerks

The city of Olean continues its own health department with a personnel as follows:

- 1 Doctor
- 1 Clerk
- 1 Inspector
- 2 Nurses

The whole is unified by a County Board of Health of seven members appointed by the

Board of Supervisors, and an advisory committee of five members of the Board of Supervisors.

Cattaraugus County is approximately square, and has an area of 1,343 square miles. It had a population of 71,323 in 1920, distributed as follows:

In cities (Olean and Salamanca)	29,782
In 16 incorporated villages	15,374
In strictly rural sections	26,167

The administrative headquarters of the County Health Department and the County Laboratory are located in the City of Olean, but in order to reach the rural sections, eight district health stations have been established, in each of which there are two or three nurses, and rooms for holding clinics and making examinations and keeping records.

One of the features of the work of the County Health Demonstration is its records. If a demonstration is to be of value, its activities must be recorded. The great weakness of the public health work done by physicians is the failure of doctors to educate the people in the nature of diseases and in the measures to prevent sickness. The great weakness of rural departments of health is failure of health officers to give publicity to the good work which they do. Every health officer performs many important items of work for which he gets no credit because he does not tell the people about his activities. The workers in the Cattaraugus County Department of Health have kept careful records of every item of their activities. They have tabulated the results, constructed charts, and made great efforts to inform the people what they have done. In no other way could they have made their demonstration of value.

The Meeting—The program of the annual meeting of the State and local committees on Tuberculosis and Public Health was unique and efficient. It consisted of an observation tour of the headquarters and district stations. In each place a meeting was held at which the leaders gave accounts of their work, and specialists from outside the county spoke. Among the speakers were Dr. George M. Fisher, President of the Medical Society of the State of New York, Sir Arthur Newsholme, formerly Chief Medical Health Officer of England, and Mr. Homer Folks, Secretary of the State Charities Aid Association. The addresses were reported by a stenographer, and are printed in the pages following this article. A person reading them will obtain information regarding every phase of the demonstration.

The Future of the Work—What will be the future developments of the work in Cattaraugus County? The present system is a demonstration, and like all other new work done on

an extensive scale, it is costly. The trustees of the Milbank Fund will withdraw their financial aid, as of course they should do, as soon as sufficient evidence is obtained to show the value of the demonstration. If the work is to go on after a year or two, it must be supported locally.

The evidence is that the County Health Department is a decided success, and that both physicians and laymen wish it to be continued.

The tuberculosis work will be extended in all its phases.

The control of communicable diseases will be done with increasing efficiency by local health officers and practising physicians, but the County Health Department will be available in emergencies and for educational work.

The laboratory will be continued and extended. At present every doctor in the county is patronizing it.

The examinations of milk and water supply, and the control of sewage will be the functions of the County Health Department.

Maternity and child hygiene work will be extended largely by educational means through the visitations of mothers by nurses.

The school hygiene work will be extended and developed as fast as standards can be developed in both the county and other parts of the State.

The nursing staff may possibly be reduced, but after all, the County is not oversupplied with nurses. The characteristic of the Cattaraugus County Nursing Service is not the number of the nurses, but their distribution to every part of the County.

The work of publicity and education will probably be conducted largely by the lay public health organization—the County Committee on Tuberculosis and Public Health, but also by the officials of the Health Department. Still it is too much to expect of human nature that the officials of the future will continue to keep such complete records and make such extensive studies as are done at present with stimulation from outside sources.

The addresses of disinterested observers at the meeting, and the convincing arguments of the leaders in the demonstration, and the actions and appropriations of the Board of Supervisors all indicate a continuance of the work.

The most hopeful sign of the continuance and expansion of the work is the attitude of the medical profession of the County. The growing concord and agreements in the trinity of health organizations throughout the State point to an increasing cooperation of physicians, health officials, and lay organizations

which in other counties will result in an increasing adoption of all the essential features of the work in Cattaraugus County.

The work in other counties may not always take the exact form of that in Cattaraugus County. The former development of health work in New York State has not been along county lines, because the county has been a minor unit governmentally, and not the major unit as in the Southern States. Still it is difficult to see how rural health work can ever be done efficiently except on a county-wide basis. Some counties are well adapted to the county unit plan, others to the city and village plan. A combination of the two plans will probably be adopted, as indeed is already being done in Cattaraugus County. That County continues its local health officers, although little publicity has been given to their work.

Extension to Other Counties—The extension of the County Health Department to other counties will probably come about through the spontaneous action of the physicians, health officers, and lay workers. A tentative plan of campaign which was proposed for Nassau County would seem to be adapted to other counties.

In the Spring of 1922 the plan of establishing a county department of health was discussed in Nassau County. It was proposed that the present local health units be continued, and that a county health department be established to consist of a health officer, two or three clerks, and a small staff of public health nurses. Headquarters were to be maintained, and Ford cars for the transportation of the workers.

The County unit was to be available for the assistance of the health officers in emergencies and in any new line of work that might be undertaken.

This plan was presented to the health officers individually, and later in a meeting of the health officers, by the Deputy Commissioner of Health and other officials of the State Department of Health, and was unanimously approved.

The next step was the presentation of the plan to the County Medical Society, which approved the plan by a large majority. However, the plan was not consummated because it was made a part of a radical proposal to change the entire county plan of government, which was defeated. The plan by itself met with favor.

If the health officers and physicians of a county will unite in asking for a county health department, to start modestly and grow from within, it should stand a good chance of adoption in any county.

"COOPERATION BETWEEN THE STATE MEDICAL SOCIETY AND HEALTH AGENCIES"

By GEORGE M FISHER, M.D.,

PRESIDENT OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

THIS is the second year in which the State Medical Society has been invited to participate in your deliberations. It is bringing about the desired results which we are looking for, and that is coordination in the health work.

I want first to congratulate this committee and make a few remarks as to the impressions that I have received as President of the State Medical Society, the first of which is the order, the promptness, the executive efficiency which you have shown in pulling off these tours and these meetings.

The second impression I want to make is the wonderful support you are getting from the laity in Cattaraugus County.

And the third impression, and that which is probably more important than all, is the support which you are getting from the physicians in Cattaraugus County. I talked with your head yesterday and he tells me that they are practically working one hundred per cent. Now, I am frank to say that that is a great deal more than they are working in any other part of the State, and I believe it is due to your work here. It is due to the great incentive which you have put among the people, and which you are driving at them at all points.

I don't know where in the State of New York there is a better place to have a meeting of this kind than right here among your hills and valleys where every phase of nature speaks of health.

At this point I want to thank the State Charities Aid Association for the work which it has done during the last campaign on medical legislation. I am frank to say that I doubt whether we would have carried our Medical Practice Act had it not been for the many public health agencies which have cooperated with us, and, as President of the State Society, I feel obligated to you and to say to you in behalf of the Society that we thank you for your many motives, your many energies, that you put forward, and the impressions which you have made upon our legislators in carrying this movement through after the many years in which it has been fought.

There is another thing which appealed to me and that is the ease with which you talk money in getting these things. Now, yesterday your Assemblyman and Chairman of the Board of Supervisors didn't seem to think it was going to be any great thing to raise the amount of money necessary to carry on this work, even though the Milbank Foundation should be withdrawn.

During the last twenty-five years or such a matter, the advancement of medicine has been at such a rapid pace that it has been one of the means of promoting and organizing different health societies throughout the country. They all have the same end—alleviation of human ills, and the prolongation of human life. This has resulted, as far as the practice of medicine is concerned, in three divisions. First, the preventive medicine, second, the curative, and third, which comes in the lay field, is education.

The Medical Society of the State of New York, which is composed of the component county societies, up to within a short time ago has taken very little active part in the work of the health agencies, the cause of which is probably due to the idea on the part of the profession that their special work has been encroached upon, and upon the part of the health agencies too much exclusiveness and not a tendency to take the medical societies into their confidence.

The individual physician is a busy man, too much occupied to study the signs of the times and know the steady trend of these activities. Many health agencies have been led to consider themselves able to carry on work without the aid of the physician as a man, forgetting that in unison there is strength. Time has proven both the profession and the health agencies are in error. The physician's prerogative is to diagnose and prescribe, in a narrow sense confined to the individual patient, in a broader sense, care and practice among people, not all of them private patients.

There has been a reluctance to undertake the latter responsibility, which has resulted in the organization of public health agencies. These agencies require a vital necessity to carry on their work, namely financial backing, which the profession, by itself, rarely can assume. The physician is ready to search out the source of illness and epidemics, direct activities that will remove factors contributing to the spread of disease, for example, his attack upon yellow fever and malaria. These problems are large and require prolonged instruction to the people, as with our present campaign against diphtheria. Physicians in such instances can be virtually mobilized to carry on the work of such campaigns, or in fighting epidemics, which was amply demonstrated in 1918 against influenza.

But back of all these activities you will find governmental or lay support, without which these investigations could not have been car-

ried on successfully. The physician should be encouraged to serve on health boards and public health committees in such instances. The medical problems are his, while the involved economic problems are for the organizations. Here is where the two organizations should meet and work in unison, miter together, so to speak.

There has been a tendency for lay organizations to secure a few selected physicians to carry on their work, while it is the desire of the State Society to give the entire profession an opportunity to work on these problems. The physician has always been willing to give technical service, to treat all who call upon him, regardless of whether they can pay for his services or not. It is his pride to serve the hospitals, and he is offering his services freely in public clinics. He is now undertaking a place in the public health activities and studying ways of informing the laity of whatever is injurious to health, and emphasizing what promotes health. It is safe to say that the medical profession is the more unselfish of all professions. Give him personal incentive in these activities and you will awaken a ministry of strength for good which cannot be over estimated.

Medical organizations and societies were originated and are sustained for scientific development of individual physicians. They

have naturally been slow in the development of civic affairs. As a function of theirs, they have always been desirous to participate in public health activities, and many times they find it difficult to prevent the appearance of striving for business. Too much attention has been given to scientific affairs and not enough to civil, resulting in a retiring tendency on the part of many of the profession, when his real tendency is to enter into health activities.

The physicians have been indebted to governmental and lay agencies, or voluntary welfare organizations, for powerful stimulation in their private work and preventive medicine. Individual physicians in the State Medical Society and other special branches of medicine are pointing the way and gradually the entire fraternity is taking up the broader task of preventive medicine. There are in all organizations those looking into the future further, and who have advanced ideas beyond the rank and file. They may be called dreamers, perhaps radicals, but it has been many times proven that they were leaders.

We are rapidly arriving at the point where the medical societies can see the value and necessity of health organizations, while the latter can see their work only begun but never finished without the aid of the medical profession. This partnership will carry the work into every hamlet.

IMPRESSIONS OF THE CATTARAUGUS COUNTY DEPARTMENT OF HEALTH

By EDWIN P. KOLB, M.D.,
HOLTSVILLE, N. Y.

THE IMPRESSIONS OF A PHYSICIAN FROM THE OPPOSITE END OF THE STATE

THE three-day session of the Annual Meeting of the State and Local Committees on Tuberculosis and Public Health of the State Charities Aid Association, was held in Cattaraugus County, June 1st-June 3rd, 1926. The Annual meeting was made the occasion for an observation tour of the Rural Health Demonstration being carried on in that County, with the advice and largely through the financial assistance of the Milbank Fund, and under the supervision of the State Charities Aid Association.

This Rural Health Demonstration being county-wide, covers a larger area than any intensive public health demonstration previously attempted.

The purpose of the demonstration is to prove that an intensive campaign, covering all phases of public health work, conducted over a period of years, by an efficient organization, following a well-planned program, and liberally financed, will raise the standard of health and physical well being of the community and

reduce the morbidity and mortality from disease. If the hopes and aims of those conducting and supporting the demonstration are attained, it will verify the statement of the late Dr. Herman M. Biggs, that "Public Health is purchasable. Within natural limitations any community can determine its own death rate." The County has been organized as a Health District with a County Board of Health, a full time County Health Officer, and a County Laboratory with a Medical Director and a corps of technicians. The County is divided into eight health districts, each having a district health station. These stations are the headquarters of the district nurses and are the clinic centers. There are at least two field nurses in each district, fifteen field nurses and four supervisors being employed. The various public health activities being carried on include tuberculosis work, clinics, consultations and home supervision, communicable disease, venereal disease, maternity, infant and child hygiene, mental hygiene, health education,

nutrition, public health nursing, sanitation and food inspection, etc. Neither the functions nor duties of the local health officers have been changed, nor have the local medical school examiners been supplanted.

The program of the session included tours to various sections of the County, inspections of the various departments of the health organization, and a series of meetings which were addressed by well known health authorities, the members of the staff of the demonstration, visiting and local physicians, and laymen. The tours were carefully planned, the local staff of the Health Demonstration acting as guides. The programs of the meetings were well arranged and the meetings were of exceptional interest. Among those in attendance who took parts in the program were an internationally known authority on public health, the President of the Medical Society of the State of New York, representatives of the State Department of Health, National Tuberculosis Association, State Department of Education and health workers from all sections of the State, most of whom took part in the program of the meeting.

The following is a summary of our impression of the demonstration.

Extremely valuable and very thorough public health and preventative medical work is being carried on in Cattaraugus County.

The organization is complete, and the personnel highly efficient.

The demonstration is unique in that it thoroughly covers all phases of public health work and is reaching the most remote rural sections of the County. Unlike some of the public health programs of lay organizations in the past, the aid, advice and cooperation of organized medicine, the State Health Department, and the general practitioners, have been warmly welcomed, perhaps solicited, and the family physician is being considered an important factor in public health work.

The demonstration is proving that the general health of any community can be greatly improved by intensive public health work, conducted by an efficient organization, with a well-planned program and sufficient funds with which to work.

We believe that the value of this work will be shown in the future vital statistic records of the County. We doubt if the apparent results of the work as shown by recent vital statistics can be attributed largely to the results of the work, for the demonstration has not been carried on a sufficient length of time for its results to be reflected in vital statistics.

It seems evident that the demonstration has the approbation and enthusiastic support of

public officials, many deep thinking, public spirited laymen, and the majority of the local medical profession. Whether this will be true after outside funds are withdrawn and much of the financial burden falls upon the taxpayers, remains to be seen.

It seems probable that when the demonstration period ends and the Milbank funds are withdrawn, considerable more money will be spent for public health work than previous to the demonstration. We predict that the County Health District with a full time County Health Officer will be continued, the County laboratory will be retained and a considerable part of the nursing organization will be employed. Probably it will not require so large an organization or so great an expenditure of money to continue efficient work. An intensive demonstration, with its large organization, elaborate machinery, and detailed work in collecting and tabulating comparative statistics, is naturally expensive. It requires considerably less power for the continued movement of a machine after it has gained momentum than was necessary to start it.

We doubt if public officials in other Counties, at this time, are likely to appropriate sufficient funds to carry on intensive public health work of this kind, unless the work is initiated with the aid of outside funds.

We think the tuberculosis case-finding program is not as extensive as it might be, in that they have not gone back far enough in locating probable sources of infection from which to work. We understand that the reported cases of the year previous to the demonstration were taken as the starting point in the follow up of known contacts. Unsuspected tuberculosis is more likely to be found in those whose contact with an open case dates back some years than in those whose contact has been comparatively recent.

The Cattaraugus County Health Demonstration has afforded the first opportunity for making a sustained study of health conditions in a county-wide district. Hitherto no one has known with any degree of accuracy, how much public health work has been carried on in any rural community, because there has been no agency available for collecting the information. The Cattaraugus Health Demonstration is like a public accountant that has sized up all items of public health work. But unlike an accountant, the Demonstration leaders have not given publicity to the defects found, but they have quietly undertaken the task of making up the deficiencies both financial and scientific. Their work has been wholly constructive, and so they have made a real Demonstration of rural public health work.

THE CATTARAUGUS COUNTY HEALTH DEMONSTRATION THE IMPRESSIONS OF A LOCAL PHYSICIAN

By A. L. RUNALS, M.D.,
OLEAN, N. Y.

I AM writing the impressions of a local physician, of the work accomplished in Cattaraugus County by the Health Demonstration and reviewed at the annual meeting of the State Committee on Tuberculosis and Public Health held in this county June 1st, 2nd and 3rd, 1926

I should state in advance that on such short notice I am unable to obtain the impressions of all of the physicians of the county, and will have to give only my own and such others as I happen to have obtained in conversation with those that I have met from time to time

There has been inaugurated in Cattaraugus County the county health unit plan, with County Board of Health and full-time County Health Officer. The program carried out has developed a system of diagnostic clinics, which have included mostly chest examinations, a system of county-wide nursing service available to all the physicians and which is of particular value in communicable disease control, health education by means of health talks and conferences, and assistance to such agencies as already existed, including a county tuberculosis sanatorium. The local laboratory has been developed to serve the whole county as a county diagnostic laboratory, as well as the Olean venereal disease clinic, which is giving county-wide service. A consultation service with portable X-ray, maintained by the County Board of Health, has been of much service to physicians by rendering X-ray service in the home in cases unsuitable for removal to a hospital or X-ray laboratory. Many tuberculous and non-tuberculous pulmonary conditions are diagnosed in this manner that would otherwise go undiagnosed or incorrectly so. I have been informed that the consultation service now includes twenty to thirty calls per month which, being made only at the request of the attending physician means that many physicians of the county find the service of real value. The fact that this service is obtainable day or night and any day of the week makes it the more valuable. At the various diagnostic clinics which are held at frequent intervals throughout the county, no applicant is given a diagnosis or advice as to treatment but he is referred to the family physician, to whom is mailed the report of the examination. I believe that is the only manner in which these clinics should be managed and that many early cases of diseases reached their physician sooner than would otherwise occur. At the venereal disease clinic no patient is accepted for treatment unless referred by a physician, and this rule eliminates the abuse of the clinic service.

The County Diagnostic Laboratory, located at Olean, equipped and manned to examine smears, cultures, and make complement fixation tests, is frequently of prime importance in diagnosis and in furnishing prompt treatment. This laboratory is used by practically every physician in the county, which in itself testifies to its popularity.

The physicians of the county have cooperated in many ways in carrying out the program. Toxin anti-toxin has been administered to about 3000 children by various local men, including all the local health officers who are cooperating in the program. Child health conferences are being held by eleven local physicians throughout the county, two of whom are physicians who are members of the County Board of Health. This work has stimulated private conferences between patients and physicians because of the health propaganda.

I am seeing far more people now than formerly who desire an annual health examination or a special examination because of a symptom that formerly they would have attempted to "wear off."

I formerly believed that the office of local health officer was solely held by the man so officially designated, but now the public at large look to their private physician for guidance in methods adopted for the prevention of disease, and he becomes interested in the prevention of such communicable diseases as diphtheria and scarlet fever, and thus is aiding in the lowering, in later years, of cardiac and renal diseases. This has been brought about by popular health education. This is an important phase of the work of the County Board of Health, and I quote from a recent address of Dr. Wendell C. Phillips, president-elect of the American Medical Association, "The new era in medicine which physicians of the future must be prepared to enter must rest on the foundation of a wide and comprehensive plan of personal and public health education."

Organized health demonstrations cannot perform their full function in a community without the cooperation of the family physician, for though the value of toxin anti-toxin and similar preventive measures may be told to every parent, it is the family physician whose opinion is asked before the consent slip is signed. The family physician, as a representative of the County Medical Society, should have proper representation on the County Board of Health and the opinion of the County Society sought on health problems. This stimulates the physician to keep abreast of all sound health movements and results in

nutrition, public health nursing, sanitation and food inspection, etc. Neither the functions nor duties of the local health officers have been changed, nor have the local medical school examiners been supplanted.

The program of the session included tours to various sections of the County, inspections of the various departments of the health organization, and a series of meetings which were addressed by well known health authorities, the members of the staff of the demonstration, visiting and local physicians, and laymen. The tours were carefully planned, the local staff of the Health Demonstration acting as guides. The programs of the meetings were well arranged and the meetings were of exceptional interest. Among those in attendance who took parts in the program were an internationally known authority on public health, the President of the Medical Society of the State of New York, representatives of the State Department of Health, National Tuberculosis Association, State Department of Education and health workers from all sections of the State, most of whom took part in the program of the meeting.

The following is a summary of our impression of the demonstration.

Extremely valuable and very thorough public health and preventative medical work is being carried on in Cattaraugus County.

The organization is complete, and the personnel highly efficient.

The demonstration is unique in that it thoroughly covers all phases of public health work and is reaching the most remote rural sections of the County. Unlike some of the public health programs of lay organizations in the past, the aid, advice and cooperation of organized medicine, the State Health Department, and the general practitioners, have been warmly welcomed, perhaps solicited, and the family physician is being considered an important factor in public health work.

The demonstration is proving that the general health of any community can be greatly improved by intensive public health work, conducted by an efficient organization, with a well-planned program and sufficient funds with which to work.

We believe that the value of this work will be shown in the future vital statistic records of the County. We doubt if the apparent results of the work as shown by recent vital statistics can be attributed largely to the results of the work, for the demonstration has not been carried on a sufficient length of time for its results to be reflected in vital statistics.

It seems evident that the demonstration has the approbation and enthusiastic support of

public officials, many deep thinking, public spirited laymen, and the majority of the local medical profession. Whether this will be true after outside funds are withdrawn and much of the financial burden falls upon the taxpayers, remains to be seen.

It seems probable that when the demonstration period ends and the Milbank funds are withdrawn, considerable more money will be spent for public health work than previous to the demonstration. We predict that the County Health District with a full time County Health Officer will be continued, the County laboratory will be retained and a considerable part of the nursing organization will be employed. Probably it will not require so large an organization or so great an expenditure of money to continue efficient work. An intensive demonstration, with its large organization, elaborate machinery, and detailed work in collecting and tabulating comparative statistics, is naturally expensive. It requires considerably less power for the continued movement of a machine after it has gained momentum than was necessary to start it.

We doubt if public officials in other Counties, at this time, are likely to appropriate sufficient funds to carry on intensive public health work of this kind, unless the work is initiated with the aid of outside funds.

We think the tuberculosis case-finding program is not as extensive as it might be, in that they have not gone back far enough in locating probable sources of infection from which to work. We understand that the reported cases of the year previous to the demonstration were taken as the starting point in the follow up of known contacts. Unsuspected tuberculosis is more likely to be found in those whose contact with an open case dates back some years than in those whose contact has been comparatively recent.

The Cattaraugus County Health Demonstration has afforded the first opportunity for making a sustained study of health conditions in a county-wide district. Hitherto no one has known with any degree of accuracy, how much public health work has been carried on in any rural community, because there has been no agency available for collecting the information. The Cattaraugus Health Demonstration is like a public accountant that has sized up all items of public health work. But unlike an accountant, the Demonstration leaders have not given publicity to the defects found, but they have quietly undertaken the task of making up the deficiencies both financial and scientific. Their work has been wholly constructive, and so they have made a real Demonstration of rural public health work.

THE SIGNIFICANCE AND VALUE OF THE CATTARAUGUS COUNTY HEALTH DEMONSTRATION TO NEW YORK STATE

By DR. EDWARD M. CLARK,

DISTRICT STATE HEALTH OFFICE, STATE DEPARTMENT OF HEALTH

Mr Chairman, fellow health workers I esteem this a very great honor and a very great privilege to represent here before this auspicious gathering the Commissioner of Health of the State of New York. There are two things that impress me very strongly. One is the great educational value that is bound to result from this movement in Cattaraugus County. The other is the demonstration of the great value of the public health nurse as an adjunct to the health doctor in doing public health work.

I am glad that the people in charge of this Demonstration have been wise enough in their day and generation to put into operation measures which enable them to employ a large number of expert public health nurses to work in the various fields of activity which this Demonstration covers.

I was struck too by the tremendously important and far-reaching program. The educational features of this campaign to me are simply remarkable and I am pleased to note that, because in my years of experience as health worker I have always maintained that seventy-five per cent of all appropriations for public health work could be honestly and wisely spent in educating the people up to the value and importance of looking after their health.

The discoveries which have been made in modern biological science have given us working tools that we never possessed before. When I began the practice of medicine forty years ago, a compound fracture of the thigh meant amputation or death, and sometimes both. We knew nothing about sepsis, that valuable hand-maiden of modern surgical practice. During the last fifteen or twenty years, we have had placed in our hands weapons by which we are able to exterminate pestilences. The work of General Gorgas and his confreres in discovering the mode of dissemination of yellow fever enabled the Government to build the Panama Canal, a feat which has won the admiration of the world. We have practically conquered typhoid fever. We are rapidly conquering diphtheria, and with the educational

work of the last four or five years we are able to go into any community almost in the State and after a little bit of intelligent explanation we can do almost anything we want to do. The people are becoming educated. They realize as they never realized before the value of health. They are coming to realize, not only the common people, but our members of boards of supervisors, our members of city councils, our statesmen in the halls of legislation and State capitols and in the National Capitol, that the greatest asset any nation can have, that any family can have, that any country can have, that any city can have, is not the material resources that are about us in this beautiful, prosperous country of ours, but the amount of physical health that the people possess. This was demonstrated largely in the World War. The whole thing is resulting in the survival of the fittest, and when I say the "survival of the fittest" I mean the healthy people who are growing up in the country today.

One of the difficulties we have to contend with in doing public health work is the meager salaries paid good trained health workers. A young man who goes into public health now, unless he has some reasonable expectation of a big inheritance, won't get very much in the way of this world's goods, and his biography is pretty certain to be written in the short and simple annals of the poor. But if he is a real trained public health worker, he will in time become imbued with the broad spirit of altruism and a love for humanity that will make him do his best work regardless of the salary he gets. That is the position the average health worker is enjoying today.

The trained public health worker who has been in the service for many years becomes so wedded to his work that after a time he is satisfied if he can get a little something to eat and a bed to sleep in. He gets interested in his work and begins to generate love for humanity, and bye and bye he begins to enjoy the fruits of his labors, and his work is a work that is never done, he must keep everlastingly at it, you cannot stop for a moment, and every day has got to be a full day.

THE COUNTY NURSING WORK

By Mathilde Kuhlman, R. N. Director Division of Public Health Nursing, State Department of Health

I HAVE visited your sanitarium many times. It has always been filled with patients who are happy and contented and willing to stay there, the doctor was interested and went there every day to see them, they had good nurses, and that there was every manifestation

in this county of human interest in this sanitarium.

It is one thing to get the patients in the sanitarium, and it is quite another thing to keep them there. I feel like carrying these

that degree of harmony necessary for the best results in group movements. Through the efforts of the County Health Department a post-graduate course of lectures has been given in obstetrics and infant hygiene, which was well attended by all the members of the county association throughout the past winter.

At the inception of this health demonstration, the point was stressed that a community can properly carry out its own health program, and to fulfill this plan I believe local men should be stimulated to acquire such post-graduate instruction and experience as is necessary to equip them to carry on in this work. This has been done to some degree, but not sufficiently in all branches. I believe the Demonstration is and will be a success. The personnel has been good, the cooperation has been good, but in my opinion there must re-

main at all times a close cooperation between Demonstration officials and local physicians, which requires effort and understanding on the part of each, and a proper appreciation of the value of the other fellows' opinion. The Demonstration officials should keep constantly in mind the fact that they at all times intend to work with the local physician, and that he in turn intends to cooperate with them.

A significant fact is that the procedure adopted by the County Board of Health to develop various phases of its program of health activities has in no way been an experiment. The program of the County Health Department has been carefully conceived, and its execution has not departed in any way from the approved methods of health department practice as carried on throughout this country.

THE COUNTY TUBERCULOSIS WORK

By ROBERT E. PLUNKETT, MD,

DIRECTOR OF THE DIVISION OF TUBERCULOSIS, STATE DEPARTMENT OF HEALTH

I feel I would be extremely ungrateful if I should miss this opportunity to express my personal feeling in regard to the success of this program which has been brought about by the well directed energies of the County Health Officer and his advisers, and the close application of work of the directors and members of the various bureaus. And I sincerely feel that a lot of the credit has been justly placed in the nurses. I do not think there is any subordinate in any public health program who is more valuable and of greater assistance than the well-trained, wideawake public health nurse.

Regarding home treatment of tuberculosis, unless it is carried on with the cooperation of the superintendents of the sanatoria and the medical profession at large, it is going to tear down the sanitarium program we have been preaching and praying for for twenty-five years.

There is need for sanatoria, as we all know, and there is a need for sanitary home treatment. We cannot get to it until we get the necessary machinery to carry it out. You can imagine what would happen in any county if we should go and talk to the individuals suffering from tuberculosis who have always and always will be anxious to stay at home, and who will say, "Why, the experts say we don't have to go to a sanitarium any more." They would all grab it, and we would as some medical men have predicted, transfer our sanatoria to institutions for the treatment of heart disease, because we could not get the patients in the sanatoria.

So I am for home treatment, but I am for home treatment under these conditions, under the proper institution. And when I say "institution" I mean not only the superintendents of the institutions, but the cooperation of the medical profession, because I care not what anyone says, unless you have the cooperation and sympathy of the family doctor you can only go just so far, and I don't care how large a program you have got. The family doctor in the small community is the friend of the family. He stands next and nearer to them than any other individual, I don't care who the individual is from the outside that comes in and talks to that family, no matter what they tell them, they may lose a little confidence in their family physician, but when they have illness in the home and they need that close friend, when he tells them what he thinks, they are going to carry out his instruction. So if any county seriously considers the institution of this form of treatment of tuberculosis, seek the cooperation not only of the superintendents, but of the family doctor. Nobody is going to replace him.

I appreciate very much Dr. Jensen's remarks concerning the children. I think that is one of our most important features in anti-tuberculosis work. There is no form of tuberculosis, and there is no program that can be complete unless it has provision for the diagnosis and care of children. I think that the work they have done in these clinics with these children is going to be an incentive to us from the outside to instigate and initiate similar programs in other counties.

IMPRESSIONS OF THE CATTARAUGUS COUNTY HEALTH DEMONSTRATION

By SIR ARTHUR NEWSHOLME; K.C.B., M.D., F.R.C.P.,
FORMERLY PRINCIPAL MEDICAL HEALTH OFFICER OF ENGLAND AND WALES

ONE fine and great feature of this demonstration is that it is an admirable combination of official work with voluntary work—such a combination in its closeness of association as I have never seen in any other locality. And it appears to me that the proper setting of voluntary work is the official framework, that inside that frame work it can do so much better work than if it is absolutely separated and outside.

The second great feature of this work here is that it is a complete public health program, it is a program including the whole and every branch of public health work. Driving, as I did, into Olean on Saturday last, the car was obstructed by a drove of Holstein cattle and every one of those cattle was marked, indicating that it had been tested for tuberculosis and found to give a negative reaction. That is an indication that the fundamental sanitary welfare of the district is being supervised and looked after, and with these fundamental conditions having been fulfilled, that then is the time for the application of the special measures which are being promoted in connection with this demonstration.

A great deal, as I say, has been accomplished. I cannot stay to tell you how much, but the possibilities are far greater than the actual realizations up to the present time.

I have devoted more than forty years of public service to public health work and during the whole of that period I cannot say that I have met any other example of work which is so complete in its organization as this, and which has in it so great possibilities of completely successful result.

A great deal can be done in five years, but I think the Milbank Trustees would be very short-sighted if they stopped there after so limited a period of trial. But meanwhile undoubtedly the most reassuring fact financially is that year by year the county and local authorities are themselves giving a larger and larger proportion to the public health work here, showing that they are keeping pace with the Milbank Trustees and thus doing their share toward bringing the total result to one hundred per cent efficiency which we all desire.

There was in this country a famous Colonel named Ingersoll, who, when he was challenged it he had to make a world how would he make it better than the present one, retorted that he would make health catching instead of sickness. That was apparently a very clever statement, but a very short-sighted one, because

that is exactly what health is. It is catching—much more than sickness. If it were not so, very few of us would be here today. The example of healthy conduct in one person is contagious with others, and the example of Cattaraugus is going to be contagious for the rest of the world. The force of example is extremely great.

Now, the objects which we have in view, as has been indicated, are the diminution of mortality. That means the prolongation of life, the enhancing of health, and the development of the full nature of man, physical, mental, and moral. And no public health policy which does not compass within its range the whole nature of man, to my mind, is not completely fulfilling its functions.

So I attach very much importance to one particular branch called the social hygiene branch of the demonstration, which has not yet been more than slightly developed. There are great possibilities in that branch of the work and it needs extending very greatly. It is work in which the clergy and ministers of the community and the teachers, in fact, every social well wisher can do excellent work, and I am quite certain that that help will be forthcoming.

One has to realize that the parts of public health work in which the least success has been achieved in the past are those in which conduct is concerned. The diseases against which we have been most impotent are those in which conduct is concerned. That is so with regard to tuberculosis, to a less degree, but the conduct is steadily improving and the standard of model conduct in fighting the possibilities of infection of other people is rapidly rising, so the deathrate from tuberculosis has been cut to half—still too high. But when we come to venereal diseases we realize we have a bane in our midst which is causing something like a fourth of the total deaths in some communities. Yet it is largely going uncontrolled. And that disease could be entirely abolished in a single generation were the standard of conduct that which everyone in this room, I am quite certain, would entirely approve.

Why is that standard of conduct not applied? I am quite certain that unless we add to our child welfare centers and in our elementary schools, and unless our mothers are fully trained in the method of training early character in childhood so when the time of temptation and storms of passion arise, there will be paths of inhibition and resistance so

things to other counties in the State that are struggling along to do the work

Miss Gamble has told you that the staff now consists of fifteen public health nurses, three specialists, the supervisor, and the director

One of the things that impressed me and which is applicable to every county in the State, is the wonderful cooperation and the unity of purpose of every single worker in this Demonstration. Mr. Nelbach is going to tell you how it is to apply to every county, but I can say that that cooperation, that spirit of unity, should exist in every county, even where there is only one nurse. It is necessary for her to work with the other workers, with the county agent for dependent children, with the home economic worker, and everybody else, and there should be that unity of purpose. All nurses should know their own work and stick to their own work. So that applies to every county.

Then, another thing which impressed me was the wonderful interest and the very active way in which the nursing committees are functioning, and that is something which is very, very important for a nurse, even one nurse in a county, it is very important that she should have a committee and that that committee should be very active.

Another thing which impresses me here and which is very necessary in any county and that is that any county where a general pro-

gram is being carried on—and that is being done more and more—it is so necessary to have a proper balancing of a health program. I feel very sorry very often for the one county nurse whom we turn into a general public health nurse because there is the urge of so many things. Quite recently two different nurses from two different counties came into my office and they said, in tears, "There is so much expected of me. I am expected to do tuberculosis, I am expected to do pre-natal and child hygiene, and the State Department of Health wants me to be active in the toxin anti-toxin program, and my committee think that the school work is the most important thing I can do and they are urging me to do school work."

Now, the school nursing is perhaps the easiest thing that the public health nurse has to do because her group is all there and it is less difficult than the work with the pre-school child, but in my estimation the pre-natal work and pre-school child work are of the very greatest importance. That and the tuberculosis work, I think, are the two outstanding things that should be carried on in every county, because, after all, school work is important and the pre-school child is the school child of tomorrow, so I feel that it is very important for the nurses to have their program arranged so they will be doing pre-school health work.

THE DEMONSTRATION AND BOARDS OF SUPERVISORS

By STANTON P. HULL, M.D.,
PETERSBURG, N. Y.

PRESIDENT, STATE HEALTH OFFICERS ASSOCIATION

WHAT has been the effect of this Demonstration upon the Boards of Supervisors throughout the State? The question is to sell the idea to a Supervisor. That can be done by education. It is a hard task to sell a man that is in the political game the idea. But if he is convinced that his constituents want him to vote to expend money, he will do it.

Now you have had the history of this county and how the Supervisors got behind the movement. What is true in Cattaraugus County will be true in other counties. They are of a similar type. They all belong to the human race, although we have been told sometimes that politicians are different, but nevertheless they want to do what their constituents want them to do, and workers from this county and those of us who have visited here going back to our own counties and selling the idea to our Boards of

Supervisors, and they have to get in touch with the lay committees, or, if the lay committees get in touch with the members of the Boards of Supervisors, and that is the only way to stimulate interest in public health work in other counties.

What effect will it have upon the New York State Sanitary Officers Association, which is composed of the health officers throughout the State? I am sure that that organization will be found in the front ranks, doing anything for public health in any county. That is their duty, their function.

As health workers, the medical man is rapidly changing. His idea of a few years ago has changed. He is getting into line on the work of public health. And just such Demonstrations as we have here is convincing all of us who are interested in public health work that the family doctor will cooperate.

nurses that that state of things can be put an end to. There ought to be no endemic diarrhea in this county, and the unborn child ought to be reassured on that point.

Then, supposing I survive to be two or three years old. I want to know what care you are going to take of me in the pre-school age. "Are you going to treat my decayed teeth?" I ought not to get any if I took cod liver oil, but supposing I did, are my teeth going to be attended to?

"Suppose I begin with slight adenoids? Is it going to be treated in the early stages, or am I going to arrive in school with adenoids fully developed, where the mischief is already largely done?"

Attention to the pre-school child is necessary in order that school hygiene may become a practicable matter.

So I may go on to the question of school life, but I needn't pursue the simile any further because you see the full importance of it. But at any rate I feel confident that although a great deal has been done, very much more is going to be done.

Dr. Fisher has told us that the medical profession was willing to cooperate in this, so that cooperation is secured, and one of the first

things that will need to be done is to ensure that active cooperation, inter-communication and cooperation between the Health Department and the private physicians, without which no complete success can be obtained.

We get together at these conferences and we talk this sort of thing, and as we enthuse together and we pass resolutions together, "Whereas, etc., etc." "It is resolved, etc., etc." Then we go home with a glow in what is supposed to be in our precordial region and the next morning we wake up and the glow hasn't entirely departed. We remember what happened and rub our hands, "Now that job is finished, what's the next thing I have to do?"

That isn't what is being done here. It is not all talking. We are conferring together as a preliminary to action, and action is going on here, and tomorrow when we go home we shall try and follow out the inspiring example which is being set us by Cattaraugus County.

I wish I could live another ten years just to see what the result of this great effort is. I am quite certain, as has been said yesterday and today, it will make history, and I am quite certain everyone here and especially the private physicians and citizens of this county will do their share in helping to make that history.

DR. NEWSHOLME'S IMPRESSIONS GIVEN AT THE CLOSE OF THE MEETING

Although I have had more than forty years' experience in public health work in my own country, and although I can say without prejudice that the general average of public health work in that country is probably somewhat higher than the general average in this country, notwithstanding that, I am constrained to say that I have never in my own country nor in the visits which I have made to other countries in Europe seen work which is exactly like the work which is being carried on here. It is, I think, the most striking example I have ever come across of active and exact co-operation between official agencies and voluntary agencies, and that is the marriage which I think ought to take place in every community when the service of humanity is concerned.

There always has been and always will be ample scope for voluntary workers. They are the pioneers. They are not shackled the same way official workers are, and the general result

is that new movements are commonly begun on the voluntary side and are gradually taken up on the official side when they become going concerns. And the general state of all voluntary movements, even the work you are doing now, is to be swallowed up in official work. But that is no sooner worked than other needs come along, and so the range of voluntary work and the progress of humanity is gradually extended.

You will need the active and steady co-operation of every member of the medical profession as well as of the general public, and the presence of doctors around me here tonight indicates that that support will be given.

I wish every success to this work, I have every confidence in its future, and I am sure that if you will continue in well doing, as I have no doubt you will, then the work here will become an example for the whole world.

far developed that unless that is done we shall not succeed in getting rid of these diseases which are largely a question of deficiency in conduct

I want to emphasize this to you that any death which occurs before old age is either due to accident or negligence, or it is due to suicide or murder. Only those three categories will include all deaths occurring before old age. Mishaps may occur, but a large proportion of deaths are murders. The person who sells whiskey when illegal to sell, and produces the six deaths which occurred from acute alcoholism in Cattaraugus last year,—murder. The person who drank that whiskey and killed himself,—suicide. And that reminds me of the fact that quite apart from any problem of prohibition, surely it is part of the program of this Health Demonstration to teach the physiological bad effect of a single glass of whiskey on any man who has any work to do. That is an accepted point right through the civilized world, that no work can be so well done with a single glass of whiskey as without it, and therefore, from the physiological and medical point of view it is part of the Health Demonstration to drive that truth home to everybody.

We sometimes hear of people digging their graves with their teeth. Many of us do it. Most of us after middle age undoubtedly eat too much, and there are many errors in our dietetics which really mean so long as we persist in them that we are going to die five or ten years earlier than we need to if we would regulate our lives as the dietitians will be able to tell us about.

I would like to take another set of illustrations. I would like to imagine myself an American child hitherto unborn and in that land from which the babies come, and I believe in that particular land before birth there is a great deal more knowledge than we know about, and I am not sure that they are not familiar with the literature which the Cattaraugus Demonstration is getting out. Well, I think you agree to those assumptions. That being so, I say to myself in that ante-natal region, "Shall I be born in Cattaraugus County, or elsewhere?" And I say, "Well, I am not so sure about that." I want to know, "Is adequate care going to be taken of my prospective mother, or not?" I don't know which mother it will be. "Are all the prospective mothers in Cattaraugus County going to be looked after during that period?" "Are the doctors going to cooperate with the nurses in order that the proper examinations and advice may be given so I may have a chance of being born alive and being born healthy?" Then after that, I, that is, the baby, I want to know next, "Am I

going to be born at the time of birth under satisfactory conditions?" I have read in some of the official reports of Dr. Douglas and other people that the odds are that seven mothers die in this country out of one thousand babies born alive, one in one hundred and thirty. I am not willing that my prospective mother should run that risk, and I had rather be born in a community like poor benighted England where the chances are only three to a thousand.

"Furthermore, I have read a great deal of medical literature lately and I learn that the use of forceps very often is dangerous when they are used prematurely, or in unsatisfactory homes, or away from a hospital where proper care can be given. Sometimes babies are born dead. I don't want to be born dead. Furthermore, if I am born alive, I don't want to have a cerebral hemorrhage which causes me to die of convulsions a month later. If I survive the convulsions, I don't want to be a blithering idiot the rest of my life. And all that may happen through difficult birth."

"Furthermore, I have heard and it is scientifically tested and proved that if my prospective mother, when she were a baby a month old, had been given a teaspoonful of cod liver oil every day during the first month of her life, she would not have developed rickets, and not only would she thus have been safe from many dangers of life and health in her infancy and childhood and school life, but also she would have been saved from having one result of rickets, a contracted pelvis which is not large enough to secure birth of a large baby, or can only secure birth of a large baby under serious difficulties and dangers to the mother. Am I going to be born the child of the mother who has had cod liver oil at the time of infancy? If not, I will wait a while."

Then our inquiring unborn spirit proceeds further. "Suppose you reassure me on those points, I want to know when I am three months old, or six months old, and my mother is no longer able to give me the natural food which is my right, how am I going to be dieted? Is the diet going to be by an old-fashioned grandmother or a doctor who learned his training even before I did, or is it going to be modern and up-to-date scientific feeding which would give me a fair chance of living to eighteen months old?" As a matter of fact, in this county there has been very little reduction from endemic diarrhea. It is one of the bad points here, and it is perfectly clear that the nurses cannot improve that without the active study and help of the private practicing physicians in this county. The nurses have to follow the advice of the doctor. It is only by combination between the doctors and

nurses that that state of things can be put an end to. There ought to be no endemic diarrhea in this county, and the unborn child ought to be reassured on that point.

Then, supposing I survive to be two or three years old. I want to know what care you are going to take of me in the pre-school age. "Are you going to treat my decayed teeth?" I ought not to get any if I took cod liver oil, but supposing I did, are my teeth going to be attended to?

"Suppose I begin with slight adenoids? Is it going to be treated in the early stages, or am I going to arrive in school with adenoids fully developed, where the mischief is already largely done?"

Attention to the pre-school child is necessary in order that school hygiene may become a practicable matter.

So I may go on to the question of school life, but I needn't pursue the simile any further because you see the full importance of it. But at any rate I feel confident that although a great deal has been done, very much more is going to be done.

Dr. Fisher has told us that the medical profession was willing to cooperate in this, so that cooperation is secured, and one of the first

things that will need to be done is to ensure that active cooperation, inter-communication and cooperation between the Health Department and the private physicians, without which no complete success can be obtained.

I wish every success to this work, I have every confidence in its future, and I am sure that if you will continue in well doing, as I have no doubt you will, then the work here will become an example for the whole world.

WHAT IS HEALTH WORTH?

By HOMER FOLK,
SECRETARY OF THE STATE CHARITIES AID ASSOCIATION
NEW YORK

WHAT does it cost you to be sick? What does it cost your families and relatives and friends? Think it over a minute

I have had two little instances in the last few weeks in my personal acquaintance. A young man—just a little out of college was trying to get his home established and own his home, his wife was ill. They couldn't afford to have a trained nurse. She wasn't ill very long, no especially complicated or very serious things, but the sum total of his sickness bill was five hundred dollars. That represented the total amount he had hoped to save that year to pay on the house, so he would own his home. It is already dated some years ahead, and that little illness shoves it another year ahead—just one little spell of illness.

Now, another dear friend of mine of many years standing, somewhat older, a bit more established, a social worker whom some of you would know, had a most serious time last summer. He had to go into a hospital and go on the operating table and be taken to pieces pretty much, and some of the damaged parts discarded, and then be put together again, and he had to have a trained nurse for quite a while, two or three of them for a while, and came home, and still had to have the nurse for a while longer than that. I met him at lunch the other day and I said, "Do you mind telling me what the damages came to?" "Well," he said, "without anything except the actual outright cost, it's thirty-eight hundred dollars now, and keeping on right along." Thirty-eight hundred dollars looked pretty big to me, and that seems to be a fair sample. When family budgets are made up, as good people make up budgets, and try to forecast what they are going to get and to spend, when they go on the rocks, isn't it more often than anything else that sickness is the unforeseen thing that enters in and queers the whole game?

We don't have to depend on individual instances that we may happen to know, because there have been some quite serious studies made this last year on what sickness costs, and that is the reverse side of what health is worth.

Some very good and conservative statisticians, on the soundness of whose ideas large businesses have been built, have taken up the question, "What does sickness cost the people of the United States?"

First, there is the doctor's bill, and the nurse, and the hospital, and the drugs and the facilities and that kind of outgo, and they have reached a conservative round figure, which

isn't just a guess but is based on a lot of details that I wouldn't bother with at the moment, that it costs ten dollars a head per year, ten dollars per man, woman, and child outgo for that kind of sickness cost.

Now, of course, besides that, there is the loss in wages, because the sick man and woman cannot work. The man who is on day wages loses his time. If he don't lose it, his employer loses it, if he continues his wages. The farmer loses that time, he falls behind getting in his crop.

On the average, two per cent of all the people at any given time are sick, an average of two per cent. You work out that percentage on the income of the country arising from work and services, and you arrive at another twelve dollars per capita for the entire country, or a total cost of sickness of twenty-two dollars per capita per year.

That is not a guess, that is a very close, careful and conservative computation. My own preliminary guesses ran quite a little ahead of that.

Well, twenty-two dollars a year a head doesn't right offhand at the first moment seem like a terribly large sum, but apply it to the population, say, of Cattaraugus County. What does sickness cost Cattaraugus County, assuming that you represent the average of the country? Well, that little figure of twenty-two dollars applied to your population works out one million, six hundred and twenty-eight thousand dollars per year. That makes fifty-eight thousand dollars spent for health look like thirty cents, doesn't it? Thirty cents is, in fact, just about the ordinary per capita expenditure for health where nothing special is going on. That is in the ordinary run of villages, cities and towns, health work runs from nothing up to one dollar a year. When they spend one dollar a year, they think they are going some. Most of them come around fifty cents a year. Sickness costs them twenty-two dollars a year. When they do a real good job, such as is being done here, all putting together in a pool, it comes to three dollars per head per year, public and private, and all put together.

So you can re-state the question, can people afford to spend one-seventh as much to keep well as it is now costing them to get well?

Then, of course, a great many times they don't get well and they cannot get well, because prevention is relatively simple and easy and relatively certain, whereas cure is quite uncertain and very expensive.

The present health cost, average of health

work, of fifty cents, average between nothing and one dollar, doesn't look very much when you measure it by some other things besides sickness. For instance, it is just the per capita cost of what the people of the United States spend for chewing gum. Chewing gum and health estimated the same value, as gauged by expenses.

Now, if they should put it up to three dollars a head for all purposes, they would then have arrived at the present per capita per annum cost of face powders and cosmetics. An expenditure which has always seemed to me wholly wasted and thrown away because nothing could improve upon those feminine works of art and beauty which God has provided for the world.

Three dollars a year is just one-seventh of what we are spending for tobacco in this country, which just about equals the cost of sickness, twenty-one dollars per head, as against twenty-two dollars.

Now why should we have any county health units? Why spend money for county health units? We have town and village health officers. Why anything more? There is one very simple and direct answer to that. It is because no one performer can be a whole orchestra. I have seen a man who played a piece of music with each hand and blew on an instrument from his mouth, and played one with each foot. He made a noise, but it wasn't music.

Now a health officer, a physician, however good he is (and he can be very useful and do very important work), cannot be at the same time, a physician, a health officer, and a nurse, and a health educator, a specialist in tuberculosis, a specialist in maternity, a specialist in mental hygiene, and all the ten or fifteen other things that you have to have to make a sufficiently diversified and rounded-out health program. You cannot get that in each town and village because a town and village couldn't afford it, and these experts wouldn't have enough to do if you had them all there. You have got to get to the larger basis of the county, to afford to have the diversified kind of service you have to have.

Back in 1908 or 1909 we had a little beginning of the Christmas Seal sale, and the first year the Christmas Seal sale brought in twenty-one thousand dollars. That looked like a lot of money, and some of us thought it would never bring in much more than that, it might reach twenty-five thousand dollars. But the Christmas Seal sale went from twenty-one thousand to thirty-one, fifty, seventy, ninety, one hundred and fifty, three hundred, four hundred and this year just closed, a half million dollars in a round sum from that one source.

When Dr. Fisher spoke of that little conference in the State Health Department, the State Health Department of New York then got an appropriation of seventy-five thousand dollars a year. Well, by 1913 we had gotten it up to one hundred and fifty thousand, and there was a great to do about it. One hundred and fifty thousand dollars for the State Department of Health! It was too much. One of the political parties, through its spokesman in the legislature, said "We are going to cut this in half, we are going to repeal this new fangled law." But before the session was over he forgot all about that. I learned afterwards there was a caucus of his party and there was one vote in favor of repealing the law, and all the others voted "No." The one vote in favor of it was that of the leader, who announced what he was going to do. That is a case where the leader didn't lead. The magnificent sum of one hundred and fifty thousand dollars was continued. That was 1914, and this is 1926. Some people thought (I was on the right side that time) that maybe that wasn't the final total that could be arrived at, that if the State Department really did a great job for health and showed themselves competent and cultivated the confidence of the people, they might get more than one hundred and fifty thousand dollars a year. Well, what did they get last year? One million, two hundred and twenty thousand dollars, annual budget for the State Department of Health.

In 1908 we had a great International Tuberculosis meeting in Washington and experts from all over the world to discuss how to do it, and the conclusion they came to was we had to have tuberculosis hospitals to segregate the advanced open cases of the disease, primarily. So we came back and went to Albany and had one of those little conferences in the evening when you get the real people together and put it before them, the State leaders, and they said "Well, it sounds all right, it sounds reasonable, but there isn't any money at all. The canals and roads take so much money, there is none left. We will let you have a county law if you want it, you can have a law for the county hospitals, if the county authorities vote to do it." I knew in my bones that they thought that was a way of *not* having it done at all, because there wasn't a man I know that really in his inmost heart thought any county would do it. But we said, "Thank you very much, that is a very good idea, probably there ought to be county hospitals." They passed that law. It was written in our office and they went over it and found it very good, made a few changes, and the law went on the books. Then David's little sling the Tuberculosis Exhibit, began to travel around the State. You had one here and one in

Chautauqua County, and I am glad to see so many people here today from Chautauqua County—and after a while a distinguished citizen of that county died and left one hundred and sixty-five thousand dollars in her will for a tuberculosis hospital, and the county added sixty-five thousand more, and about a half a dozen years ago a member of the Tuberculosis Committee of Columbia County died and she left a million and a half to establish a tuberculosis hospital, not limited to that county. There were twelve hospitals that were started by voluntary contributions like that, in twelve different localities, some of them fine places, and most of them turned over to the public a little later, with a lot of public money put in to supplement it. And I am rather more proud of the rest of it. Besides the twelve, there were twenty-four counties where the boards of supervisors, acting on their own initiative, or after a vote of the people, established a county tuberculosis hospital, outright, straight governmental public institution, making a total of thirty-six local tuberculosis hos-

pitals established since that year of 1909 when nobody thought anybody would put any money into tuberculosis hospitals. And those thirty-six hospitals have involved an expenditure for their construction, not for operation, for their construction alone and the grounds and building and plans of nine million, nine hundred thousand dollars.

So I come back to it that you never can tell what the people will spend for health if you show them the results. The rash man is not the man who says the people will do it if they are shown, the rash man is the man who undertakes to put a limit on what the people will do when you show them the facts.

And to this State-wide group of citizens and members of Tuberculosis and Public Health Committees and public officials from all over the State, the one thing I would say to you as you go back to your localities and face your authorities and your citizens on the question of better health is this: Don't let the reproach ever be made to you, "Oh, ye of little faith."

STATISTICAL ASPECTS OF THE DEMONSTRATION

By E. C. BURNHAM, M.D.,

ASSISTANT IN PREVENTIVE MEDICINE OF THE COMMITTEE ON TUBERCULOSIS OF THE STAFF CHARITIES
AID ASSOCIATION

ONE of the first of the vital statistics we consider in any locality or community is the general mortality rate, the rate of deaths per thousand population. There it is for a series of years, 1915, 1916, 1917, 1918, running up to a high rate at the time of the epidemic of influenza to something over eighteen deaths per thousand population, then gradually coming down to about what it was before, running along 13.8, 14.8 deaths. I notice from 1923, 1924 and 1925 a fairly slight but fairly significant drop.

The next one, the "Leading Causes of Death." This is to know what to do and what the problem is. Here we have heart disease, the greatest cause of death in Cattaraugus County. These are the figures for 1925, causing 196 deaths: cerebral hemorrhage, 90, accidents, 84, cancer, 84, nephritis, 75, premature births, 70, pneumonia, 61, tuberculosis, getting rather low, 35, arterial diseases, 31, diabetes, 19, other causes, 177.

Next, "Maternal Mortality." That is a chart showing the number of deaths of mothers per thousand births. It went up high in 1918 because the influenza epidemic caused deaths of mothers as well as of other people and caused more deaths of mothers because they were in a weakened condition caused by the birth of the child. The number runs along in 1920, 1921, 1922, 1923, up to six deaths per thousand births, then dropping down in 1924 and

1925 to four deaths in Cattaraugus County, making a rate of 2.7 deaths per thousand births. Of every thousand births in Cattaraugus County, less than three mothers die.

Next the "Still Births." Here we have figures showing the still birth rate of babies born dead per thousand total births. Here you see the figure running up, the total births of 1,544, to fourteen or fifteen hundred a year. The still births in 1915, 67, 54, 62, 63, 58, 60, 74, 66, and then in the last three years, 44, 50, 37. Thirty-seven still births, a rate of 25.2 still births per thousand births in Cattaraugus County, compared with forty-one still births in New York State. The still rate has dropped, the mortality rate has dropped.

Now, the infant mortality and infant deaths. Infant mortality rate is a rate which we use quite commonly in public health work, the number of children who die under one year of each per thousand births. The number of children who die under one year, of each per thousand deaths. That is, we have per thousand live births in 1925, 1,399 live births, and we had 103 children dying during that year a rate of 74 per thousand. Now, if you go back to 1915, the infant mortality rate was 88, 74, 82, 94, 81, 83, 79, 95, 93—practically the same thing up to and including 1923, and then in 1924 a drop to 65, a saving between 1923 and 1924, if you will, of approximately twenty-eight deaths, twenty-eight babies saved that

year A little higher the next year, but still low That is a statistical fact The rates have been going along about usual, and for some reason during the last two years they have been much lower

Then we study to find out where those occurred and we find when these deaths occur We find that of the children who died in 1925, thirty-five out of one hundred and three died less than one day of age—34 per cent of all the children who died in 1925, died under one day of age Twenty-six children, or 25 per cent of the total died from one day to one week Thirteen children, or 13 per cent of the total, died from one week to one month Now to find out how many died during the first month, you must add together the thirty-five and the twenty-six and the thirteen, and it gives you a figure of about eighty-one or eighty-two, thereabouts, more than three-quarters of the children, or about three-quarters of the children dying during the first month What does that mean? We go back to our medical training and we say if the children die early it probably means the need of more pre-natal care, need of better nursing care and other health care during child birth, and possibly better feeding care on the part of the mothers We must make further studies of that

The causes are shown below of the same one hundred and three premature birth, malformed, weak, that is what we call congenital debility, which means a weak child at birth who cannot carry through, and other cases which you see very clearly there

Now, the Tuberculosis Chart Here we have the tuberculosis deaths The first column represents the number of deaths from 1911 to 1920, the second representing the number of deaths in 1921, fifty-five deaths, the third, the number of deaths in 1922, fifty-three deaths, for 1923, fifty deaths, for 1924, fifty deaths, 1925, thirty-five deaths Notice that a drop in the one year of fifteen deaths, a drop of about one-third of the total deaths from tuberculosis That is a statistical fact That means something

During 1917, sixty-one cases of tuberculosis were reported The law says when a physician diagnoses a case as tuberculosis, it must be reported to the State Department of Health He must report it This shows the number of cases reported 61, 54, 81, 72, 73, 77, 85, and in 1924, 343, 1925 192—more cases being reported What does that mean? Does it mean you have a lot more tuberculosis than before? We say "No" because your deaths haven't increased It probably means a search is being made, that the nurses are going into this home and that home, saying, "You are under-weight", or "You are having a chronic fever and ought to

be examined" and sending those people to the physicians and the physicians are reporting the cases We study and say we ought to have at least three cases reported for every death

The important thing is that we have got more cases reported and no evidence of an increase of the disease

The next chart, "Accidental Deaths in Cattaraugus County" I think that is of interest to everybody Notice the accidental deaths in 1917, almost one hundred deaths, in 1918, 1919, 1920, 1921, the number of accidental deaths decreasing I don't know the cause Possibly the boys being away at the war, less people in industry, may be the reason We had quite a slump in industry The purple color represents automobile accidents, the green represents railroad accidents, and the yellow represents all other accidents Now, in 1923, 1924, there was a marked increase in accidents, and in 1925, the number of deaths about eighty-four, not an unusually important number and not as high as some years

There we haven't done very much as far as the Health Department goes We have done little to prevent accidents There is a real problem which we are tackling We can see where these accidents occur Some occur from the age zero to four, two deaths in males and two in females—probably children falling against the stove and things of that sort Deaths, five to nineteen, four in males and four in females The death-rate of children in cities is apt to be much higher The dangers to children from five to nineteen in cities are greater

Now, then, you have seen all of these You have noticed the slight decrease in the annual death-rate You have noticed a decrease in the maternal death-rate You have noticed less still births You have noticed that the infant mortality rate is decreasing, that deaths from tuberculosis are decreasing All those things are favorable things All those things we want to bring about We know from long experience that they may be caused by better health work They may be caused, however, by some other things and it is not easy to say now definitely that those things are caused by health work and by nothing else Economic causes, men have better food, men have more leisure, possibly they are not pressed as hard at work, but if you look at these charts and see the drop in deaths, the drop in infant mortality, you are pretty apt to say, like the man did that was kicked out of the dance hall, "There is something going on in Cattaraugus County," and it is a reasonable thing if something is going on in Cattaraugus County that this health work is doing a good part of it

TUBERCULOSIS WORK

By WILLIAM C JENSEN, M.D.,
OLEAN, N. Y.

DIRECTOR, DIVISION OF TUBERCULOSIS, CATTARAUGUS COUNTY HEALTH DEPARTMENT

THE first organized effort in tuberculosis control in Cattaraugus County started in 1908 in the organization of the voluntary Cattaraugus County Tuberculosis Association which confined its efforts really to two projects. One was creating sentiment toward the establishment of Rocky Crest Sanitarium, the other was the treatment and selection of advanced cases. You all recall about that time we thought the solution was to take care of the advanced case and forget the rest. Unfortunately, this organization was short-lived, but the work went on because the next year the Olean Anti-Tuberculosis Association was organized and is still very much in existence. It carried on in the same way, emphasizing the Sanitarium for the open advanced cases.

In 1910, the first full year of operation of the Olean Anti-Tuberculosis Association, the huge sum of \$683.32 was spent for tuberculosis work in Cattaraugus County. In 1912, the next real step was the organization of a Health Camp. About that you have heard and I will say nothing any more than I do believe it is one of the best projects carried out in this country. In 1916, the work of the Olean Anti-Tuberculosis Association that was really started by the old defunct County Association, bore fruit in the establishment and opening of Rocky Crest Sanitarium with twenty-two patients. In 1920, the Cattaraugus County Public Health and Tuberculosis Association was organized. The same people in the first organization were back of the second organization, with many recruits. In 1918, the County added to their staff a county tuberculosis nurse. In 1922, the county was spending \$1.37 per capita for health work. If you have followed the charts prepared by the State Charities Aid, you can compare that with the case today.

In 1921, there were one hundred and thirty-five cases examined in the county, exclusive of Olean, and one hundred and eleven examined in Olean. That gives you the scope of the work that was being carried on. The total number of clinics was forty-five in Olean, and only seven in the county at large. In 1923, periodic clinics were started by the late Dr. Bartlett, and during that year there were four hundred and eighty-four people examined, five hundred and eleven examinations, and forty-seven cases of tuberculosis were found. The next year the first real year, the examinations increased to two thousand, eight hundred and ninety-nine, the number of cases found, to two hundred and seventy-eight. The next year, 1925, the third year of the demonstration, the number increased to three thousand, one

hundred and two examinations, and two hundred and fifty-eight cases.

The average number of deaths in Cattaraugus County from tuberculosis, exclusive of non-residents in Harrietsburg, has been around fifty. This chart shows you the average of about forty-nine for that decade. For the years previous to the demonstration, fifty-five and fifty-three. The first year of the demonstration, the mortality was fifty, the second year, twenty-four, last year, thirty-five, or a rate of about 47 per 100,000 population.

The number of cases reported in Cattaraugus County from 1917 on is shown in this chart 61, 54, 81, 72, 73. The year before the demonstration, the number of cases reported was 77. The first year of the demonstration, the number increased to 85, the second year, the number increased to 343, and in the third year of the demonstration, it dropped to 192. The reason, of course, is obvious. That year was the first year of intensive case finding. It was natural that we would locate a lot of unreported cases, and if we did a good job that year, the next year we would have some decline. This year I am sure we will have about the same.

This chart illustrates the progress of the diagnostic clinics. In the first year of the demonstration, the first clinic was held in Franklinville in March, by the late Dr. Bartlett. Later ones were conducted by Dr. Wang and later by Dr. Douglass. That year, nineteen clinics were conducted. That is exclusive of a few conducted by the Olean Anti-Tuberculosis Association previous to March. There were only four or five. The first year of the demonstration, the number increased to one hundred and forty-four. By that time the county had been organized into six health districts. Besides that, there were a few industrial clinics that year.

The next year the number increased to one hundred and seventy-four. The reason for that is purely because of special work done in the schools of Olean in the underweight survey which I will describe later, and on the Indian Reservation. The physical examinations increased from five hundred and eleven the first year of the demonstration, to two thousand, nine hundred and eighty-eight the second year, and three thousand, one hundred and two the third year. The total number of persons examined, four hundred and eighty-four the first year, two thousand nine hundred and eighteen the second year, and the grand total at the end of the third year was five thousand, three hundred and forty-six.

The number of tuberculosis cases diagnosed increased from forty-seven the first year to two hundred and seventy-eight the second year, decreased to two hundred and fifty-eight the third year, and this year I expect we will have another slight decrease. It is only natural that we should

X-ray examinations were made by a portable X-ray that can be taken to all the stations and into the homes. The first year, one hundred and ninety-three patients were X-rayed, the second year, nine hundred and fifty-six, and the third year, six hundred and eight. The examinations increased, but the X-ray examinations decreased. At first, we would X-ray anybody that the doctors wanted us to, or if they themselves asked. Besides that, we X-rayed advanced active cases. We changed our policy and discontinued X-raying the perfectly obvious positive cases and cases we were absolutely sure that were inactive. That explains entirely this decrease.

The chief reason for the success of our tuberculosis work is, no doubt, the nursing service. At first, practically all of our cases were gotten into the clinics, came into the clinics because of the nurses. They were ferreting out the suspects and practically every case came from that source. In 1923, the nurses made one thousand and three visits in the interests of tuberculosis patients. In the second year, they still maintained their case-finding interest and the number of visits increased to one thousand, three hundred and sixty. The total number of cases increased from two hundred and thirty-seven in 1922 to three hundred and eight this year (indicating) to four hundred and sixty-seven in 1924, and in 1925, to five hundred and thirty-eight.

The next year of the demonstration we began to notice that the doctors began to send more and more cases. They always did send a few, but last year a total of eighteen per cent of all cases were referred by the doctors. This year it is already forty, referred by the doctors.

In 1925, the nurses made fifteen hundred and ninety-two home visits to tuberculosis patients, this year the nurses made some fourteen hundred home visits, which gives a total of three thousand visits to homes of tuberculous patients.

This chart shows the cases by health districts. As you notice Olean, with the largest population, has twice as many tuberculous patients as any other district, 221. Salamanca, the second largest city has about one-half, 112, and so on. The curious thing is the fact that the rate in this county where conditions are about the same, with the exception of Salamanca and Olean, the rate is so much higher in some districts, chiefly Cattaraugus

and Randolph, than the other rate, also, that the lowest rate is the second city, Salamanca, 83.884, practically the same rate as our two smallest districts. I was asked what the reason was. I know of no other reason except that the nurses of those districts having less people to work with had done a better case-finding job.

The tuberculosis work in this county is based first on the finding of cases, second, on their classification, and third, supervision and treatment. In order to carry out such a program, we have organized the following services. First, the case-finding clinic service which I have described, second, the consultation service available at all times to all physicians, including the portable X-ray service wherever there is proper electricity. Our machine operates on sixty-cycle. Occasionally we go into a home with twenty-five cycle and we are of no service. Third, school medical service. In school medical service, we attempt to examine all school children that are more than ten per cent underweight, or patients referred by the school nurses, regardless, all patients referred by the school principals and teachers, regardless, all patients we feel who have chronic symptoms, and we are going to examine all habitual absentees.

Treatment—Insofar as available, we recommend sanitarium treatment for all active cases. Rocky Crest Sanitarium, started in 1916, with a capacity of twenty-two. In 1918, it had an authorized capacity of twenty-six, with actual patient days of six thousand, nine hundred and twenty-eight out of a possible number of patient days, nine thousand, four hundred and ninety. In 1923, the first year of the demonstration, the capacity was increased to forty, patient days possible, fourteen thousand, six hundred, and actual patient days, thirteen thousand, three hundred and ninety-two. It shows a considerably better utilization of the sanitarium than in the early days. In 1925, the capacity was increased to fifty beds, the possible patient days to fourteen thousand, nine hundred, and utilization of actual patient days, fourteen thousand, seven hundred and eight. That shows we do not forget sanitarium treatment.

We have already examined over three thousand, two hundred children in Cattaraugus County. Nineteen hundred of those children have been examined in the clinics, thirteen hundred have been examined in the schools of Cattaraugus County, seven hundred and thirty-six being underweight.

Outside of the finding of a general nature the findings in tuberculosis are very, very outstanding. You will notice in the children from ten to fourteen per cent underweight, five hundred. Eighteen cases of tuberculosis were

found, or 36, which is just about the number of cases of tuberculosis you will find in that number of people at large, if you include all stages and types. Percentage of underweight in children, fifteen to nineteen, one hundred and eighty-one. Nineteen had manifest tuberculosis, 88 per cent were definitely tuberculous. As the percentage of underweight increased, twenty to twenty-four, the number decreased, but the percentage of tuberculosis increased to approximately 21. We had twelve children, 25 per cent or more underweight. One was 31 per cent. Out of this twelve, three were diagnosed tuberculous. We found one which we diagnosed "suspect." Those cases are more than all the advanced active cases found during the entire Framingham Demonstration. I have all those three films and later on I will show them.

One of the results of our tuberculosis work has been an increased admission at Rocky Crest Sanitarium in the number of cases treated, and a slight decrease in deaths. As a matter of fact, we can forget that. If you will notice there was in 1917, thirty-nine admissions. Last year, we had eighty-three admissions, again emphasizing the fact we do not neglect sanitarium treatment.

Next. Another very significant fact in the Sanitarium is the fact that previous to the Demonstration over forty per cent of all cases were active and advanced. Last year, the percentage of active and advanced cases was fifteen—quite a decided drop. Likewise, the percentage of cases at Rocky Crest before the Demonstration was running from twelve to fifteen. Last year it was forty-eight, showing a decided increase in the curable cases of tuberculosis. We cannot do much for the advanced cases other than make them comfortable. The early case we can do a lot for, and that is what we are concentrating upon.

The other phase of treatment is our home treatment plan. There are some in this audience who are very much interested in that because one gentleman told me he didn't believe in it. I invite him to discuss it. However, our

home treatment plan is based on the fact that you cannot treat all cases of tuberculosis in a sanitarium for the simple reason there are not enough beds, secondly, if you did have enough beds, a vast majority of T B patients will not go to a sanitarium. What are you going to do with that large group, certainly not forget them. Therefore, we have divided all our cases into three groups. First, all cases that live up to the requirements of Dr Paterson's sanitarium home treatment plan which you are all familiar with. Briefly, they are these. Home conditions satisfactory, financial conditions satisfactory, cooperative, intelligent, some member of the family intelligent, and a preliminary period of education, instruction, treatment in the hygiene of tuberculosis in the sanitarium, these cases preferably to be early stages and may be moderately advanced.

Our second group is that very same group, with the exception that they never went to a sanitarium, refused to go to a sanitarium. Our third group is all-inclusive—every other case, even the incorrigible. They are even the incorrigible for we do not believe we should forget the incorrigible, even if we can get only a word in occasionally. Naturally, in this group the treatment varies. It includes quite a few advanced cases, hopeless prognosis, requiring considerable bedside care of our nurses, includes many arrested cases who refuse to believe the diagnosis, who frankly tell us we are wrong. We neglect nobody. Those arrested cases we intend to follow up for a period of three or four years to determine, if possible, a survey of reoccurrence of activity in these arrested cases, following their usual occupations.

In the sanitarium home treatment group I, we have about forty—very small—for the simple reason that the vast majority of cases when discharged from the sanitarium are not fit to go into Group I. We put them into Group III. We have a follow-up record forwarded to us from the sanitarium in which it is stated frankly by the superintendent of the sanitarium whether or not he believes that patient will follow out sanitarium home treatment.

THE NUTRITIONAL WORK IN CATTARAUGUS COUNTY

By JOHN C GEBHART, New York
SECRETARY ADVISORY COMMITTEE ON NUTRITION

THE nutrition program is one of the most recent developments in the field of public health. About ten years ago Dr Emerson of Boston conceived the idea of what he called the nutrition class method. He had been working in the Massachusetts General Hospital with children, where there were a number of children who were not tuberculous, who were not cardiacs, who had no observable physical de-

fect, and yet who weren't doing well. They were under-weight, pale and anaemic, and he found that the remedy for treating that condition was not the giving of medicine, but getting these groups of children together in what he called nutrition classes and having the mothers attend them also. He worked out a very interesting method of teaching health and nutrition to those children, emphasizing the

proper means and kind of food, having the children make out records for every day in the week of exactly what they ate, what time they went to bed, and their habits of play. These children then met together once a week and checked up on their health habits and on their gains in weight. That method attracted a great deal of attention. It came to New York City and Bellevue Hospital experimented with it a while. The Association for Improving the Condition of the Poor became interested, and introduced the method in the Mulberry district. It spread very rapidly throughout the country.

When the Milbank Fund Foundation appointed a Committee on Nutrition it charged that Committee with the responsibility of considering the question of the advisability of a nutrition program for this demonstration.

We are coming more and more to realize in our health education work that the schools can be really a great factor in putting over a program of health education. Some of us believe it is just as much the business of the schools to teach children to be well as to read and write and to do figures. And we believe that if the teachers are given the proper training, particularly if there are individuals, voluntary organizations, and others who can stimulate them and give them fresh material, that a great deal of health education work can be done much more effectively through the regular channels of the school organization. It was recommended therefore that the nutrition worker should use the schools in every possible way.

The first step in the nutrition program was to make a study of just what the dietaries of the families are who are living in this county. That suggestion wasn't received so cordially at first because we had visions of a number of people going through the neighborhood and asking all sorts of questions and it might not lead to much. Instead of bringing a host of investigators into the county and asking a lot of seemingly impertinent questions, the plan was to use the people of these home demonstration groups to collect the necessary data in their own homes. These mothers had been working on various problems and they were intelligent about it and glad to cooperate.

When it came to the selection of the schedule to be made out, again we took something that had already been in use, the score card worked out by Cornell University and in use in the families in the district. The various families were asked to cooperate and we got at first one hundred families who took part in this interesting check-up one week. They recorded the food purchased and eaten by all the members of the family, and an accurate record of the quantities consumed during one typical

week was provided. Then these cards were tabulated by people who are expert in dealing with that sort of material. That study has just been completed and will soon be ready for publication.

I want to point out that we divided the people of the county into three different groups—those living in towns or cities, those living in small villages, and those living in rural districts. We found some very interesting variations in the dietary of those groups, and those variations discovered in the study have already influenced the work we are doing. For example, in the rural districts it was rather surprising to find there were less green vegetables used than in the villages. Immediately that pointed out what we needed to do with people living in the country districts, viz. simply show them how by planting the proper kind of vegetables, and using a bit of ground around the house, they could easily raise a supply of vegetables, thus showing them how, without any additional expense, they could improve their dietaries.

Again, another remedy which immediately suggested itself was the proper storage of food during the winter. A great many farmers raise quite a quantity of vegetables during the summer, but because they haven't developed proper storage methods, vegetables are wasted. It was a simple matter to show the farmers how by the expenditure of a very small amount of money, storage facilities could be provided. Steps were immediately taken through the county fairs, and in other ways, to show the people how more vegetables could be raised and stored for winter use.

A plan has been agreed upon whereby the nutrition worker should give ten days a month to work in the schools. Miss Odell has been dealing with teachers in training. I believe it is the custom for certain teachers to take training while teaching in methods of pedagogy under the supervision of the State Department of Education. Those teachers who are going to be teaching the children of the county in the next twenty-five years have thus been reached and have become interested in the work we are doing and moreover have been taught methods by which they can get this knowledge over to the children and how the subject matter of nutrition and health can be worked in with the other things they are required to teach. There is no reason why arithmetic, English and other things cannot be taught through the medium of health education as well as any other subject matter.

Miss Odell has prepared a series of lessons and lectures which have become part of the training of the teachers of the county. That I think is going to have a very far-reaching

effect. It is fundamental work and it will last for a number of years.

An important part of nutrition work has been the giving of health talks and lessons to the children themselves. We realize the more fundamental thing is probably to reach the teachers and train them so they can teach health, but at the same time in order to give the teachers an object lesson, a certain amount of educational work has been done directly with the children. For example, in the past year in this way seventy-seven schools in this county have been reached. During this year, ninety-six health talks have been given.

Another very interesting feature of the work has been the development of the school lunch program. A school lunch program in the rural school district is something very different and more important than in an urban district. Many children come great distances and it is a very simple matter to have them bring vegetables, milk, and other articles of food, and then use the preparation of these foods as a means of teaching the proper selection of food.

The teacher can be used also in helping to prepare the lunch, which they eat together. The school lunch has become a very valuable means of instructing the children in the essentials of nutrition.

In the past year and a half approximately one hundred and fifty school lunches have been started largely as a result of this nutrition program.

The nutrition worker now gives four days a month to Home Bureau work. The Home Bureaus have two definite projects: they attempt to get the mothers interested in clothing and household economy, and also in nutrition. Nutrition has been made a major project upon which these various groups are now working. In that way the workers are reaching the mothers and getting them interested in the proper diet of the children. This work is going along very successfully and having far-reaching effect.

Another very important part of the work of the Nutrition Division is the co-operation with the Nursing Division. As I have said, it was the judgment of the Committee that the nutrition work should permeate all the things being done in the area and we felt that was certainly true in a program which provides for a generalized nursing scheme. Therefore eight days out of the month of the nutrition worker's time have been given to working with the trained nurses who serve different parts of the area, largely as a consulting adviser on definite problems that come up, for example, dealing with the diet of the expectant mother. The nutrition worker makes suggestions for problem cases indicating what alterations in

the diet are needed. These particular cases are then used for discussions and for teaching methods, so that a great deal of this information and the manner of dealing effectively with the nutrition problem is being taken over by the nurses themselves, so that they in their contacts with the sick and with their groups and committees are tending to emphasize the same point of view as the nutrition worker.

There are besides various miscellaneous groups with which the nutrition worker is concerned, for example, the Parent-Teachers Associations. Many of the Schools now have organizations of the parents. These are called Parents Associations and Parent-Teachers Associations. The nutrition worker spends a good deal of her time in meeting with these groups, in holding informal discussion, and in giving demonstrations in the proper selection of food. Granges, Federations, and other community and neighborhood groups are also used as vehicles for carrying on this important work.

I want to give you a few of the figures which are illustrative of the volume of the work. For example, in the first six months of 1924, five hundred and eighty persons were reached through the Home Bureau, in 1925, six hundred and eighty, and in the first three months of 1926, four hundred and ninety. In the two years, one thousand, seven hundred and fifty persons have been reached through Home Bureau service.

Again, the work done in the school has grown in volume. In the first six months, ten hundred and forty children were reached in the schools. In the year following, two thousand, six hundred and thirty, and the first five months of 1926, one thousand, three hundred and sixty-four—a total of five thousand and thirty-four children reached since the nutrition work was first undertaken.

Work was also done with individual cases, largely in co-operation with the nurses, cases of constipation, cases of arranging the diet of expectant mothers, cases requiring patients with diabetes, and other illnesses, and extremely underweight and mal-nourished children. There were one hundred and twenty cases in the first six months. In the year following, there were two hundred and forty, and in the first three months of this year, one hundred and twenty-five, a total of four hundred and eighty-five.

In the miscellaneous group, nine hundred and twenty-five individuals were carried since work was started.

During the past year, there were one hundred and six meetings with home bureau groups, and a total of one thousand eight hundred and twenty people reached. Six hundred and nineteen people were interviewed.

outside of meetings, nineteen community nutrition meals were prepared for a total of six hundred and sixteen persons

Fifteen exhibits of various kinds were arranged and displayed in various parts of the county

As far as results are concerned, the records show there have been one thousand, three hundred and thirty-four definite changes brought about in the diet of individuals, one hundred and thirty-six children are found to be in better health as a result of the right food selection

I think that from this brief outline you will perhaps get some idea of what we are trying to do through the nutrition service. Of course, the question will be immediately asked by

some, "Do you believe this work is fundamental enough to recommend in other counties?" My experience with this question has gone back over a number of years and I think there is no question but what a rural county, or an urban district of any size, cannot claim to have a complete and well rounded health program if it does not make some provision for expert guidance along the lines of nutrition. That doesn't mean we must have an elaborate system or a large staff of highly trained individuals, but that there must be someone available for every community who is an expert in this question and who is intelligent about getting that knowledge over to the various groups in the community

HOW TO CONDUCT A CAMPAIGN FOR A COUNTY HEALTH DEPARTMENT

By GEORGE J. NELBACH, New York
ASSISTANT SECRETARY STATE CHARITIES AID ASSOCIATION

FOR those here in this room desiring to have their home county get some of the things which you see of value here, including the county health department, a more intensive case-finding campaign for tuberculosis, a more adequate staff of public health nurses, let me suggest how to go about it. This is based on experience that covers now some eighteen years of campaigning, of promoting, of organizing for more health work in our State.

The first step is naturally to get your own county association to favor it. That might mean their doing it on your say so, on your reporting back to them what you have seen and heard here, on your giving them literature about the Demonstration which you can obtain from our office. If they are not convinced, then our recommendation is to have a committee appointed to come out here and see as you have seen the work at first hand.

Now, granted that they are interested, what is the next step? Why, of course, it is to turn to the public authorities, the county board of supervisors, and tell them what you want to have done. Now they won't do it right away, because they represent different parts of the county. They are responsive to public opinion and as there is no public opinion about these things yet in your county, they won't take a decisive or affirmative action. It will be up to you through your group to create this favorable public opinion that will justify them, as the appropriators of public moneys, to make the appropriations for this kind of service. Go to them first—ask them to appoint a committee of their number to investigate the need of the thing, the things that you want to have done. That will mean a committee of three or

five persons. Then go to that committee and ask them to come to Cattaraugus County and see for themselves what is going on here. While they are doing that, your next step will be to bring home to the people through the channels of publicity and education, like the newspaper, its editorial columns, its news columns, its cartoon services, its special feature articles, the facts about Cattaraugus. It will mean talking to the ministers and other leaders and molders of public opinion, the facts about Cattaraugus and persuading them to join in this chorus of public approbation and encouragement for the establishment in your home county of what Cattaraugus is doing.

You can bank upon the whole-hearted support and assistance of your State Committee. We have had training in a number of ways and been through a number of campaigns in work of this precise nature. A number of us have gone through campaigns as intensive as those involving referendum campaigns, getting the people to vote in an election booth on a definite proposition involving the appropriation of public funds, and whatever the experience and service that we can bring to bear upon helping you is at your command.

In conclusion, let me on behalf of our State Committee express appreciation to you and to your county organizations for having you come here and see this enterprise and to express appreciation to the boards of supervisors who sent their delegates, and to the various State Departments for sending their representatives, and, lastly, I want to express a real personal word of appreciation to the various men and women here in Cattaraugus County who have helped so effectively in making this meeting of our State Committee a success.

THE SPIRITUAL VALUE OF THE DEMONSTRATION

By JOHN A. KINGSBURY, New York
SECRETARY, MILBANK MEMORIAL FUND

What are the achievements of this past quarter century which are less tangible but none the less real? What the spiritual achievements? Insulin for diabetes, vaccination against typhoid, toxin anti-toxin for diphtheria, education in right conduct which prevents tuberculosis and education in moral habits which will prevent syphilis and gonorrhea—those methods and those things have all been discovered or developed in this last quarter century

Think of it, ladies and gentlemen! I wish it were possible for us to really realize what that means in spiritual values, but just to put it in the merest material terms it means that in this country of ours during the past quarter of century, death on the average has been postponed six years. To mention only two of the spiritual enrichments of life resulting measure what that means in misery prevented, in sorrow that has not been endured

That is what has happened—just to give you a glimpse of it, just to take a glimpse at life's enrichment due to the scientific achievement of the past quarter century. That is what the Norge symbolizes to me. Oh, if we could

only make Cattaraugus County a symbol, a symbol of the spiritual values that will come to those who practice health, in spiritual values that are within the grasp of the people of this country, of this State, and of this Nation, of this world. We ought to do it, and we will do it. It is being done today. Witness the distinguished guests that have come here from all over the state, from other states, and other nations. That is already indicative of the significance of what is going on in Cattaraugus County.

Sir Arthur Newsholme said many things in his delightful way, which we shall never forget, which we shall carry away, which we shall print in our programs from year to year as slogans to remind us of our duty and of this day. Paraphrasing, I wonder if this wouldn't be a good slogan, "Make Cattaraugus Contagious." Let's quit saying, "How-do-you-do?" when we meet each other. Let's say, not in a jesting way, but looking into each others eyes, man to man, and woman to woman, "How is your conduct?" I am afraid some of us would wither under such searching gaze.

IMPRESSIONS OF THE WORK

By C W MUNGER, M.D.
DIRECTOR, GRASSLANDS HOSPITAL, WESTCHESTER COUNTY N. Y.

I HAVE been absorbing new ideas and new information so rapidly in the past three days I think it is premature for me to try to give you any accurate impressions. I think I have got to take all this literature home, digest it, and study it, and then perhaps write out a report that may be of some value. At any rate, my prediction is I am going to be able to tell a good deal when I get back to Westchester.

Our County of Westchester has a reputation among some sections of spending money rather prodigally and doing things in public health on rather a large scale. I feel, however, that we have a great deal to learn from this demonstration. We have approximately six times the population that Cattaraugus County has. We have one hundred and ten nurses, divided up among twenty-four organizations. A county nurse, who is also part of my department, has the pleasant duty of correlating the work of those twenty-four nurses' organizations. She has got a man's size job. It will never be done, of course, under the present arrangement.

The work that has been accomplished I feel

is quite phenomenal, and it is a work that I can join this procession that one of the speakers spoke of, of compliment. I think it is a work all of us in this State are going to appreciate very much. I have been particularly impressed by the interest shown by the local communities.

The most interesting and touching thing to me in all this program has been what these people in the local communities have said about the Health Demonstration. If you are putting it over to them, you are getting it across. That is the problem we are all going to have—to get it over to the people. If we can do that, we will have all the money and appropriations for health work that we need.

It is going to give me great pleasure to go back to Westchester and report in a rather dual capacity to the Department of Public Welfare about what it may be able to do to the Charter Committee, which is now trying to draft another charter, and report to the County Committee on Tuberculosis and Public Health, of the very wonderful work which Cattaraugus is doing.

IMPRESSIONS OF THE WORK

By ARTHUR W TOWNE,

DIRECTOR ONONDAGA HEALTH ASSOCIATION, SYRACUSE, N Y

I WANT to speak for just a few minutes from the standpoint of other counties. We represent various places where Cattaraugus County standards are not prevailing, where the Cattaraugus County machinery has not been set up,, and I think the question uppermost in our mind is not as to whether it is going to be desirable, but as to whether it is going to be possible for us to induce local authorities to set up such machinery and maintain standards on the high levels that prevail here in Cattaraugus County.

I want to ask one or two questions from the standpoint of other places. The first question is, "Do the people in my county—each of you can ask of your own people—have a consciousness of the public health problem?"

Sir Arthur Newsholme is quoted in a little pamphlet which we in Syracuse published on the occasion of his visit last week. One of the quotations is "Public health work, whether voluntary or official, is dependent on public opinion, and instruction of the public health matters must form a large part of every public health program."

I believe one of our first duties is to educate our public and instill an appreciation of the importance of public health.

In our counties, what do we think of when we talk about public health? In one county it may be tuberculosis work. "Are you doing public health work here?" "Yes, we have a sanitarium and doing public health work." Another county we ask them, and yes they are doing it there, taking care of the babies, doing pre-natal work and infancy work, and there the story stops.

Are they doing venereal disease work? Are they doing school nursing? Are they getting into industrial hygiene? Are they carrying on mental hygiene education? That is something they haven't thought of.

In my county we are not thinking of public health work in the rural parts of the county in a comprehensive way. Each individual has grown a pair of lungs, he has got legs, he has adenoids and tonsils, they may get diseased, he has got something in his head that may get out of gear. So we have lots of things. People all over the State are the same kind of individuals as in Cattaraugus County, and in order to protect the health, we have to have a comprehensive program.

Cattaraugus County has statistical interpre-

tation of the facts. These very highly colored and harmoniously colored and beautiful charts are based on accurate record keeping, an accurate knowledge of just what the facts are. It costs money to make those charts. It costs money to keep those records. The public health nurse cannot spend her time keeping records. Perhaps no county in the State can keep the adequate, complete, illuminating records we have in Cattaraugus County. Yet all of us have access to some information. We can write to Albany, or go to our local agencies and get some information and put it down in black and white. If we cannot make graphs and charts, we can get someone to do it. Mr. Nelbach and Dr. Burnham will be glad to help, I am sure.

That is going to be effective in translating the facts to the boards of supervisors and to the representative citizens and to the newspaper editors, getting our facts in useable shape, because, after all, whatever we get out of a conference like this is useful only insofar as it is useable, and we have to be able to find our facts.

This county has over two hundred school districts. My county has five hundred school districts. Each of those is a little health unit. Then we have lots of towns. They are health units. We have villages. They are health units. It is impossible for the health official, be it a doctor, nurse, or what not, in any one unit of that county to carry on an intelligent, effective, comprehensive work. In the first place, no place in the State, unless it be that rich county of Westchester or Suffolk County, can afford to pay the salary and command the services, we cannot get the skill, we cannot get the time. People are crossing lines all the time. Children live in this town and go to school in this next town. A man works in this town and lives in this town. Our germs and all kinds of things are carried back and forth. It is a problem that can be dealt with intelligently only by using a larger area, at least the county as the unit.

When we go back to our home towns and counties, the thing we want to strike for and strike for hard is a county organization. It has got to be a county plan and county unit, and we have got to have adequately paid workers, beginning with the county health officer, and then having such number of public health nurses as may be necessary, and all the other accessories.

IMPRESSIONS OF THE WORK

BY HUGO A. BROWN, EXECUTIVE SECRETARY, BUFFALO TUBERCULOSIS ASSOCIATION

THE people of Cattaraugus are to be congratulated in having the facilities for the expert care and treatment of all of the people in the community

Public health work brings us down to the question of how many nurses we can afford to put in the field. That is the impression I have gained here, that all the work which has been accomplished, including, of course, the experts, has done because of the large field of nursing which has been placed in this community.

Now, those of us who have been interested, especially in tuberculosis and public health work, know that that is the fact. The various clinics that we have been able to hold in the community where people never knew what a clinic was, in fact, some people wouldn't know what a physician was or a nurse—we have been able to go in the small towns and pick up ten or fifteen. We could only do that by sending a nurse in the community to work out the cases.

I was very much interested in the statement that Dr. Jensen made when he said during the course of his remarks that all of the examinations for diagnosis, and all the active cases are referred to sanitariums for treatment. I was under the impression, and it has gone out quite broadly throughout the country, that home treatment is the prevailing rule and recommendation. I was glad to be corrected on that and have my impression changed, that all active cases are referred to the sanitarium. If you cannot get them to go, home treatment is resorted to. We have done that a number of years.

I was also very much impressed when the specific instance was cited that one of the young ladies who was examined here was formerly a resident of Buffalo and had been examined by an expert in tuberculosis, and she came to Cattaraugus County to be diagnosed and treated. Now I agree with that. That has been one of our problems. The difficulty has been to get people to an expert, and to draw the line as to whom we consider expert enough to diagnose a case of T. B. We have a lot of quacks in Buffalo, unfortunately, and we have a lot of people who believe in medicine and who will go to these quacks, because we are not in a position to tell them whom to go to. This Demonstration proves through the publicity bureau you can educate the people. We have got a big job on our hands.

If you could take the physicians, if you could use enough influence and the entire organization get together through a State Committee, and take some of this expert advice we are receiving here, and which we all acknowledge is very good, and organize that into a speakers' bureau whereby all counties, for instance, Erie County, I am sure in saying if we could have a committee of three or four experts, who have the knowledge of Cattaraugus at their elbows, and who could appear before the finance committees of my supervisors, there would be no difficulty in going before that board of supervisors and asking for an appropriation of one hundred thousand to put twenty nurses in the field of the County of Erie outside the City of Buffalo, and we would receive it, and I believe a great many other communities would do the same thing.

THE DEMONSTRATION FROM A PASTOR'S POINT OF VIEW

By REV. MR. MICHAELSON, Ellicottville, N. Y.

I AM impressed in our own locality with the pleasant and effective and earnest personality of our local nurses. To have them go into the homes, to offer kindly and wise advice in the practical problems that face mothers and parents, is a real joy and a real privilege and a real pleasure, and I count us fortunate to have them in our community to help us out.

As I go about my ministerial work in the county, particularly in this district, I go even into the district schools, and I notice the nutrition posters put up on the walls for the instruction of children. I have noticed particularly one poster. It has a large potato with its eyes wide open and the hand upstretched, going hand in hand with celery and lettuce and cabbage heads. I suppose

the suggestion is that you and I ought to eat more leaves and green stuff.

I am heartily in favor of the nutrition proposition and I am quite enthusiastic about eating leaves and grasses, and so forth, but having learned to eat them, I wish some one would teach me to enjoy them.

I want to speak of the cooperation of the teachers. I have mentioned the charts I have seen in the schools and I find that the teachers throughout the county are much interested in the work and taking an active part in it. I have found also in my pastoral calling that the people living in the county in their own farm houses are increasingly interested in the work that our nurses are doing in this Health Demonstration.

is putting on. It is only this last week that I talked with a young mother. Her child was born not many weeks ago, and she said to me with deep earnestness, "I don't know what I would have done if it hadn't been for the help of the county nurses."

Now I know personally that there is no period in the life of any woman so sacred and so fraught with peril and so fraught with worth and importance as that period about the birth of a child, and a mother who is looking forward to bringing into this world a child and hoping he may grow into noble manhood or into noble womanhood is tremendously concerned that she shall be able to give to him or her the right health and right strength and right character, and is tremendously appreciative of the things the county nurses are helping to do in that particular field.

There is one instance brought to my attention of a remarkable piece of work the Health Demonstration is doing—the case of a girl who for nine years has been a cripple, trying to do her best with a club foot, trying her best and doing remarkably well, to care for a bed-ridden mother. Through the instrumentality of our nurses and the Health Demonstration she has been sent to New York once and again for treatment and has just come home able to walk even without crutches or a cane and pronounced well—a tremendously fine piece of work.

May I speak of the toxin anti-toxin treatment I listened a year or two years ago, to Dr. Armstrong speaking on toxin anti-toxin treatment and giving a stereopticon lecture. I became convinced that the toxin anti-toxin treatment was a good thing, and so during the past year we have had our own boy given that treatment. He has had all three treatments given to him and I have observed that in the receiving of that treatment that he has been caused practically no pain at all, not even a noticeable amount, and that he is just as well or in better health than before, and we have the added assurance that he shall be protected against that dread disease. There have been one hundred and seventy other children in this district who have received that treatment completely, and there are one hundred and forty now receiving it, and I hope every boy and girl can receive that treatment. I would not for the moment, now that I have seen it given, wish to have my child back and not have it given to him. If diphtheria should come into this community and that boy of ours should take it because I had been careless not to give that treatment, I could never face my fellow man nor my God again. I feel confident now that he is immune. I can thank the County Health organization, the Milbank Fund, our local physicians and heads of departments that I have had that privilege.

IMPRESSIONS OF THE DEMONSTRATION

By E. P. KOLB, M.D.,
SUPERINTENDENT, SUFFOLK COUNTY SANITORIUM

THE thing that has impressed me up here in Cattaraugus County is the extent of your program. We have done some work in Suffolk County fairly well, but it has been strictly anti-tuberculosis work, for we did not have the machinery or money to do a general public health work. The important work here is the fact that you are covering all phases of public health work and covering it very thoroughly.

The question was asked the other day whether a county could support this movement after the Milbank Fund was withdrawn. I would say the county boards of supervisors will appropriate money when the people want to have them appropriate it and when the value of the purpose has been demonstrated.

I think it has been proved here that if you have the cooperation of the medical profession and of the community at large you are bound to get what you want from the board of supervisors. You may not get as much money as you are spending now. I think after the Demonstration has been carried on for several years it won't require as much money to carry

on practically the same amount of work. I think Cattaraugus County will appropriate the money sufficient to carry on this work, and it will be an example which the rest of the State will follow.

CHAIRMAN NELBACH: Dr. Kolb, can you tell us in two minutes the extent of your case-finding work in Suffolk County? I think the figures you quoted to me on the train Monday night would be interesting to this group.

DR. KOLB: We started by getting a list of the deaths and reported cases for the period of 1914 to 1918, inclusive. That gave us over five hundred to start with. We attempted to get in contact with the known cases of tuberculosis. I must say we have never yet caught up on our program. With the new cases we have been finding, we have never reached contact with all the families in which there has been a case of tuberculosis. We have examined a pretty large percentage of them, I think. We have listed now six hundred and thirty cases that we classed as definitely cases of tuberculosis. Some of those cases in chil-

THE RURAL HEALTH DEMONSTRATION IN CATTARAUGUS COUNTY

The rural health demonstration of Cattaraugus County was the subject of the annual meeting of the State and County Committees on Tuberculosis and Public Health of the State Charities Aid Association held on the first three days of June. The Medical Society of the State of New York and the State Department of Health were officially represented on the program.

The meeting was the occasion for a report of all phases of the work of the Cattaraugus County Department of Health, which is unique in that it is promoted largely by lay agencies. The plan is that after it has been in operation for five years, the governmental agencies shall take it over.

In addition to the County Health Depart-

ment, the local health boards continue to function as in other counties, but they are supervised by the County Health Officer.

There is no precedent by which to judge the demonstration. The future success of the work will depend very largely on the encouragement which the leaders of the County Public Health Organization give to the practicing physicians, and the meeting gave abundant evidence that the county health officials desire to meet this condition. While the demonstration is supported largely by outside agencies, there is every reason to believe that the county will continue the work after outside support has been withdrawn.

GEORGE M FISHER.

dren have hilum tuberculosis, but a majority of them are definitely pulmonary tuberculosis. In addition, we have listed about six hundred and sixty cases, I think, that we class as suspect or observation cases, cases in which the symptoms lead us to believe they are probably tuberculous, which have not been followed up further by X-ray.

CHAIRMAN NELBACH Tell us what is the average annual number of deaths from tuberculosis in your County, excluding the cases who died in the two State Hospitals for the Insane, so as to enable us to compute the ratio of living cases discovered to the average annual number of deaths?

DR. KOLB The actual number of deaths in 1925 was sixty-four. The population by the State Census was one hundred and forty-three thousand. That gives us a death rate per hundred thousand of 44.7. It gives us a ratio of known cases to each annual death from tuberculosis of about 10, and suspect-observation, about 10, that is, within a fraction of ten each.

When we started in 1918, the number of deaths, I think was 98, which gave us a death-

rate of about 94. The rate has been reduced in Suffolk County from 94 per hundred thousand, to 44.7 in 1925.

In our clinic work we are working with only the sanitarium staff, plus the aid of two nurses who are furnished to us by the County Tuberculosis Association, and we are holding about sixty clinics a year. In addition to that, I have a great many cases sent to me at the sanitarium by the physicians, or brought to me by the nurses for examination.

Last month, we held four clinics and examined ninety-eight patients. In addition to that, I have sixty-one cases that I saw, most of them at the sanitarium. I went out to a few with a physician in consultation.

A great deal of work can be done by the machinery that we already have in a great many counties, but it means a willingness to do hard work. Better work can be done if we have a better organization, and it would be a fine thing if all the counties could have an organization along the lines of the organization here, and I hope that it may be possible to have that time come. You are doing a wonderful piece of work here, there is no doubt about that.

A YEAR OF PROGRESS

By **STEPHEN A. DOUGLAS, M.D.**
HEALTH OFFICER, CATTARAUGUS COUNTY, N. Y.

During 1925 the growing program of the county health work has required a steadily increasing amount of time and effort on the part of the County Board of Health as a whole and of the individual members of the Board in particular. This has resulted in a closer, more intimate contact of the Board of members with the work being carried out in the field, which in turn has benefited the work and greatly strengthened the county health program.

Early in the year, at the request of the President of the County Board of Health, the Chairman of the Board of Supervisors appointed a Health Committee of five members, who were given the responsibility of keeping in touch with the official health work being carried out in the county. The members of this committee attend the meeting of the County Board of Health, receive all reports and are keeping closely in touch with the work. It is anticipated that this close relation to the two Boards will make for a wider understand-

ing of the health problems of the county, and a stronger official organization.

Fundamentally, the success of a health department depends first upon its program, secondly upon its personnel, and finally, upon its appropriations. The health officer is almost never limited in his activity by lack of adequate laws and regulations. It is with the plan, the people, and the pocketbook that the health officer must needs chiefly concern himself. For success in making a proper plan, in selecting and training proper personnel, and in securing adequate appropriations, it is obvious that the health officer must have not only intuition, energy and initiative, but real technical preparation for his difficult and vital task.

A sound program and plan of operation is a vital necessity in rural health administration, the importance of which cannot be over-emphasized, and just in so far as this principle is applied will real results definitely demonstrate themselves.

cial standing We are now in the stage of developing a public health service for the ignorant

The hygienic education of the people is a medical problem of the first magnitude, and its solution is not yet in sight It is practiced to only a slight extent by individual doctors, but there is a growing realization of the possibilities of its practice by organized medicine The medical education of the people was the burden of the inaugural address of Dr Wendell C Phillips as President of the American Medical Association, and it is the topic that is the most often discussed in medical societies

The most important subject in popular medical education is that of leading people to accept the discoveries of modern medicine and to seek their application in their daily lives Physicians already know how to prevent a majority of cases of illness and death, except those due to old age, and their success is brilliant in yellow fever, dysentery, typhoid fever, and a few other diseases Equal success could be attained in most other diseases if the people would give full cooperation and support to the doctors

Evolution of methods in public health resembles that in animals and plants Every conceivable method of public health work has been advocated and tried, but only the best survive Some leaders in public health have rode the foremost crest of every wave of medical progress, only to see it roll back and disappear as another futile wave appears Only the slowly rising tide of knowledge of both science and human nature is potent in public health

It was only natural that men of vision and financial means should organize societies for the purpose of applying modern public health methods and demonstrating their usefulness Nursing associations were formed and every conceivable method of work was tried Clinics for every ill, real and imaginary, were opened by boards of health and philanthropists, and even pastors of churches tried faith healing in cooperation with scientific doctors Various forms of the practice of medicine by the State were developed, and were tried and found wanting Doctors often opposed the measures and sometimes supported them There was evolution in violent action during the past two decades—but out of it all has come a survival of the fittest methods and a recognition of their proper place by both doctors and laymen

The American system of civic progress is that a new movement shall be promoted and demonstrated by an organization, and its value tested and proved before the government is asked to assume its operation A frequent source of misunderstanding regarding these experiments is that the plans are published widely and the impression is given that they are perfect to the last detail A demonstration always has features which are unsuccessful—in fact, one object of the demon-

stration is to detect the imperfect features and eliminate them before they are proposed But no one knows beforehand just which features will be successful and which will be impractical While publicity is necessary in order to secure the adoption of a plan of public health work, yet doctors and people are likely to compare the achievements with the rosy promises of sanguine promoters The word *demonstration* implies a perfection of plans and methods of work, and a final exhibition of their working based on previous trial However, most public health demonstrations are also experiments made with a purpose of perfecting details by actual trial under working conditions

It is also a source of misunderstanding that public health demonstrations are usually worked out by experts who deal with great matters of administration, and are not familiar with the details of dealing with sick individuals The family doctor has too often been neglected in laying out plans for public health work He is the big element in the situation, and public health workers are now beginning to realize that his cooperation is necessary State medicine is doomed, as well as the practice of medicine by public health nurses and social workers and pastors Physicians form the only group that come into intimate touch with the people medically The doctor's influence far exceeds that of the public health nurse and the department of health

What ever may have been the attitude of the family doctor in the past toward the practice of public health and civic medicine, his present attitude is one of approval A doctor as a individual can do little in the way of practising civic medicine, but a medical leader is powerful when he speaks in the name of the medical profession through his county medical society Too often in the past have the local doctors and county medical societies been ignored in forming plans for public health work in a community But possibly this was only one phase in the evolution of methods of public health work during the time when all methods were on trial, and many disappointments and ill feelings were engendered by inevitable failure of some details

The evolution of public health has now reached the stage of standardization Laymen recognize the value of the leadership of family doctors, and on the other hand, physicians rely on lay organizations to do the work which belongs to them Departments of health, too, are fully recognized in the trinity of public health forces The stormy days of evolution are happily passed, and out of them have come standardized methods and friendly relations among all classes of workers

The present issue of this Journal is devoted principally to a description of the demonstration of the first County Health Department to be established in New York State—that of Cataugus County The amount of work done is

PUBLIC HEALTH METHODS IN NEW YORK STATE

The past two or three years have seen the clarification and standardization of public health work in New York State. Two of the most striking developments have been the practice of public health by medical societies, and the institution of a state-wide system of graduate medical education. Those two lines of achievements have gone on gradually and only a meager record of their evolution has crept into current public health literature published by departments of health and lay organizations. This lack of publicity is due largely to the modesty of physicians, who prefer to publish results rather than intentions.

It is an item of great importance that the physicians of New York State, acting through their medical societies, have reached an agreement with departments of health and lay organizations that each member of the trinity of public health forces shall respect the fields of work of the others. Physicians will

attend to medical and surgical cases which are discovered by departments of health and lay organizations, and in addition they will be ready to give medical advice to the other organizations along administrative and other lines. The fact of such an agreement is a basis by which the whole public health work of the State may be harmonized and coordinated.

The evidence of the sincerity of physicians in their participation in public health work is the graduate education system which is available to every county medical society through the cooperation of the State Department of Health. The courses are practical and emphasize the practice of preventive medicine by family doctors. The response to the courses is most gratifying and indicates that the physicians of New York State are taking their proper place among the practitioners of Civic Medicine and Public Health.

THE EVOLUTION OF PUBLIC HEALTH WORK

There was no science of public health before the days of bacteriology, and there was no practice of civic medicine until investigators had proved the causes of sickness in many classes of diseases.

Sickness was thought to be a private matter up to a generation ago, and it still is so considered by many doctors and the majority of citizens. The saying that anyone who breaks the laws of health deserves to suffer, is the development of the principle of American independence. But the logical sequence of that line of thought is that the whole community which permits a defiance or neglect of health laws will suffer—both the guilty and the innocent.

The first civic measure for the prevention of diseases was the quarantine by public authority, and from its adoption in emergencies has grown the universal plan of departments of health, and of health rules and laws enforced by legal authority.

People are willing to submit to law in the presence of danger that is evident and immediate, but not everyone is willing to submit to procedures which involve annoyance, discomfort, and expense. There are pacifists in public health, just as there are in national defense. There are those who do not believe in the preparation of vaccines and antitoxins for use in the warfare against contagious diseases. The acceptance of modern methods of disease prevention depends on education—a knowledge of the causes of diseases, of Nature's way of defense and of the methods used by doctors to produce immunity. Law is nec-

essary for the ignorant, in order to compel obedience.

The object of a law is to set a standard before the people as a goal to be attained with pride and satisfaction. A standard implies education and teachers.

The principal department of health official during the era of law was the *inspector* who was in reality a police officer. When standards began to take the place of laws, the principal department of health official became the *public health nurse*. Few people ever saw a health inspector unless trouble had actually developed. Everybody sees the public health nurse, from school children to the aged sick.

The public health nurses and the organizations which employed them, went among the people urging them to seek medical relief from their physical defects, and often prescribing for diseased conditions. The doctors as well as the people were unprepared to take serious notice of minor defects or of slight illnesses which might develop into crippling conditions. Doctors were already familiar with the cry of quacks that persons were "threatened" with fatal diseases and they had no desire to exploit sickness. Nurses could warn the people and send them to their doctors.

Health examinations and clinics for the reasonably well found little favor among physicians during the early days of public health nursing. Doctors had always felt the duty to serve the *poor*, but they had not yet begun to realize their duty to the *ignorant*, regardless of the financial or so-

MEDICAL PROGRESS

Occupation Diseases of the Physician—Julius Levy gives a timely account of the affections to which the medical man is peculiarly exposed in the exercise of his calling. Since this is manifold, the physician does not compare with the artisan who may simply be forced to assume a trying position in his work or be exposed to unhealthy chemicals or dangerous implements. The medical man is not confronted with this sort of a hostile environment, but is forced to lead an unhygienic life nevertheless, having no regularity in sleep or meals, and being under mental strain. Thus he is believed to suffer especially from high blood pressure and angina pectoris, but the author passes this over briefly, more space being given to the hazard of contracting contagious diseases. Trub once collected 669 cases of physicians inoculated from their syphilitic patients in various ways. Glanders or farcy is far less dangerous, at least statistically, for in 106 cases of human infection directly from animals only 14 were in medical men. Infection at the autopsy table and from cultures of virulent bacteria in the laboratories is well known, but not very common, most of the transmissible diseases have been contracted at some time or other, including the bedside infections. Laboratory men have contracted plague, glanders, typhoid, typhus, etc., from cultures. Septicemia from operating, from autopsies, etc., is one of the best known and most frequent infections. In like manner laboratory men and surgeons who use strong antiseptics have often been severely poisoned. The accusation that medical men are peculiarly liable to contract drug and alcohol addiction is only too true, Levy thinks, though his experience with drug habituation among the laity is evidently limited. The author mentions further acute poisoning from voluntary experiments with powerful drugs as well as accidental poisoning with the same, and concludes with the pathology of the rontgen rays.—*Medizinische Klinik*, April 9 and 16, 1926.

Treatment of Rickets With Rayed Milk Powder—P Gyorgy, of the Heidelberg Pediatric Clinic, refers to his own earlier papers on the treatment of rickets with rayed fresh milk and to the contemporary efforts in this direction of Hess, Kramer, Steenbock and Daniels, of the United States, and Cowell and Webster-Hill, of Great Britain. The first use of ultra-violet rays was in the experimental rickets of rats. Then Cowell, Kramer, and

the author each independently made the discovery that milk can be "jecorized" or given the therapeutic values of cod-liver oil by exposing it for 24 hours to the rays in question. While cod liver oil itself and the hormone treatment often fail us the "jecorized" milk has proved itself thoroughly dependable. Recently the author has worked with milk powder, fresh milk, and has found not only that it does this thoroughly but that, by spreading the powder in a very thin layer, the time need not exceed 45 to 60 minutes. Gyorgy has now treated 40 rachitic children successfully, and tabulates the full particulars in 20 of these cases. The patients sometimes received first a course of the simple unrayed milk powder as a control. This powder was always quite inert. After beginning the use of the rayed powder, the cases were controlled by the rontgenologist and by chemical analysis of the blood serum with reference to calcium and phosphorus retention. This may be placed approximately at 10 mg and 5 mg respectively per 100 cc for healthy infants. The clinical cure of the patients was checked up by the rontgenograms and blood finds in every case. The author is unusually confident in assuring the reader that rayed milk powder will cure both florid rickets and tetany with almost mathematical precision.—*Klinische Wochenschrift*, April 23, 1926.

Antirachitic Activation by Ultraviolet Rays and Sunlight.—In a review of his own experiments and those of Huldinsky and Hess with reference to the action on calcium metabolism of the ultraviolet rays and of sunlight, Steenbock (*Physical Therapeutics*, May, 1926, xlv, 5) reiterates the conclusion that the antirachitic effect of light is brought about through its action upon the inactive vitamin D. At present he is inclined to believe that this vitamin represents more than one compound. The ability to become antirachitically activated is resident in compounds of a lipoidal and unsaponifiable nature. Various sugars, glycerides, water, salts, gelatin, alcohol, ether, and petroleum cannot be activated, these do not contain the lipoidal unsaponifiable compounds. But evidence has been accumulated by the author and by Hess showing that cholesterol can be made antirachitically active. Cholesterol occurs extensively in nerve tissue, is widely distributed in the body, and is found in large amounts in the skin. Steenbock has demonstrated to his own satisfaction that secretions

commendable, and the methods which have been evolved are worthy of imitation. Anyone wishing to extend a public health service into rural districts will find a record of every phase of similar work actually done in Cattaraugus County.

It is not claimed that the Cattaraugus County Demonstration is the last word in County Departments of Health—the promoters would deprecate that idea. It is rather a practical exhibit of what results will follow the application of city methods to a rural community.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

The New York State Journal of Medicine for June, 1901, contains the following letter from a senior physician giving the expenses of a beginner during the first three years of his practice:

"Sir—Many of the newly graduated in medicine have often asked me what the beginner should do to attain professional and pecuniary success. It may not be inappropriate to sum up the requirements to success as determination, prudence, patience, industry, and energy, before telling the beginner that he should devote not less than two hours each day to study, including general literature and the perusal of medical journals, be a constant attendant at the meetings of some medical society, secure a dispensary appointment for a limited time, pay assiduous attention to his clients, and give a reasonable amount of time to his social duties. He should not think of taking up a specialty until after eight or ten years of general practice."

"The subjoined statement from the account books of a thrifty, economical, well-equipped young physician, three years in practice, will show the result of compliance with these requirements:

First year's income	\$1,000	
Contributions	50	
Office rent	300	
Other expenses, such as board clothing, etc	600	\$950
Balance in Savings Bank December 31st		\$50
Dispensary work for which no money was received, but which, if paid at half his ordinary charges, would		

amount to three thousand dollars. This charity in kind, added to the gift of fifty dollars, swells the charity account to three thousand and fifty dollars. Not many persons in easy circumstances give as much as five per centum of their incomes, nor do they give any more valuable time to charity than this struggling youth has given.

Second year's income	\$1,200	
Charity account	60	
Office rent	300	
Necessary expenses	710	\$1,070
Balance in Savings Bank December 31st		\$130
Third year's income	\$1,500	
Charity account	75	
Office rent	300	
Necessary expenses	800	\$1,175
Balance in Savings Bank December 31st		\$325

"In these three years he had saved more than five hundred dollars bearing interest at four per centum, and had given up his dispensary appointment in order to have more time to devote to his increasing practice and to study. That young man is on the high road to success, and those who may follow his good example, will surely succeed."

How many young doctors now-a-days have five hundred dollars in the bank at the end of three years? Possibly this case, too, was unusual, else it would not have been recorded.

Retrograde Capillary Pulsations in Heart Failure—A retrograde capillary pulsation, one coming from the venules back into the capillaries, seems not thus far to have been described. Such a case has been studied by C S Danzer (*American Journal of the Medical Sciences*, May, 1926, clxxi, 5) in a patient suffering from mitral stenosis, probably associated with tricuspid insufficiency. The capillaries of the skin were visualized by the Lombard-Muller-Weiss method. By this technique the subpapillary venous plexus was made very prominent. The venous portions of the capillaries were especially dilated. In one capillary under observation the corpuscles altered their course, taking first the normal then the reversed direction. In a number of other capillaries there was a periodic acceleration and slowing of the blood stream. There were phases when the corpuscles coming from the arterial limbs of the capillaries collided with those regurgitated back from the venules into the capillaries. This was obviously the result of venous stasis and regurgitation attending tricuspid insufficiency. Such a collision of corpuscles in the venous limbs of the capillaries is never seen in health. These findings prove the existence of back pressure in the venous system. This fact assumes great importance in the differentiation between circulatory failure due to back pressure (venous stasis, right-sided cardiac failure) and that due to diminished vis a tergo (left-sided heart failure). In the latter case no such signs could be present. The pressure in the capillaries was determined by the Danzer-Hooker method with the microcapillary tonometer. As the capillaries were compressed the first stage, or beaded flow, was followed by the fourth stage, reversion of the blood stream, both of these were intermittent instead of continuous. The fact that both stages were periodic is the essential pathological feature of the observation. It is probable that a retrograde capillary pulse is sufficiently characteristic to be used diagnostically in obscure cases of tricuspid leakage.

Serum Treatment of Tetanus—Jonathan M Wainwright (*Archives of Surgery*, May, 1926, xii, 5) finds from a study of British and American statistics that tetanus is rare in the ordinary type of industrial wounds, it does not occur sufficiently often to warrant urging routine prophylactic injections in all industrial wounds. We must, however, accept the possibility of tetanus arising in the most unexpected cases and rely only on the possibility of improved curative treatment. Although the war proved beyond question the value of prophylactic injections, there has been considerable doubt as to whether antitetanus serum has any real curative value after symptoms are established. This pessimism is largely due to two factors (1) Antitetanus

serum given intraspinally is harmful and diminishes the chances of recovery, (2) when the serum is administered by less harmful methods it is usually given in doses so small that it cannot be expected to be of any benefit. In 190 cases compiled from the literature, which were treated with 10,000 units intrathecally in a single dose, the mortality was 59.5 per cent, or practically the same as for patients receiving no serum. There is an increase in the death rate when intrathecal injections are added to any other method of treatment. In 90 cases compiled from the literature or reported directly to the author, when 30,000 or more units were used intravenously the first day of treatment, the mortality was 32 per cent. If this dose is not completed till the end of seventy-two hours, the mortality rate rises rapidly, though even so it does not reach the hospital average. Given by vein in doses from 30,000 to 50,000 units or more, according to the severity of the symptoms and the time since onset, it will divide the present mortality rate by two or three, or more. The efficiency of this dose will depend upon the promptness with which it is given. If the initial dose has to be repeated it should be of approximately the same size and by vein only. In the last days of convalescence intramuscular injections are allowable. The best sedative is chlorbutanol, in a dose of 30 grains (1.95 gm) dissolved in hot whiskey by mouth, or 75 grains (4.87 gm) in hot olive oil by rectum, repeated sufficiently often to keep the patient relaxed and drowsy until the danger is past.

Influenza in Infants and Children—During a recent epidemic of influenza which largely attacked infants and children, James Burnet (*Archives of Pediatrics*, April, 1926, xliii, 4) had unique opportunities for making observations. He found the incubation period short, in one or two instances twenty-four hours, the temperature high in the majority of cases, prostration and apathy and lethargy well marked. Three clinical types of the disease were distinguished. (1) A *catharrhal type* was the commonest, it was characterized by running from the nose, a dry, hard cough, which was extremely irritating, and in some instances vomiting and diarrhea. In older children headache was complained of. This type more than any other had a tendency to develop otitis media. (2) A *cerebral type* was noted in which the symptoms were meningeal, there being twitching, drowsiness, and stupor, with high temperature (105.5°), and in two cases convulsions. (3) A *colic type* showed symptoms quite out of the ordinary. The child complained of colicky pain in the region of the umbilicus, which gradually became more intense.

can be activated but that the radiation cannot penetrate skin itself, also that the exposure of goats to ultraviolet rays markedly increases the antirachitic value of their milk. While olive oil can be activated by exposure to the rays, the antirachitic value of cod-liver oil is not increased thereby. Experiments have demonstrated that not only is little, if anything, gained by exposing cod-liver oil to irradiation, but that with excessive exposure, the antirachitic properties of the oil may actually be destroyed. Cod-liver oil is so potent in the antirachitic agency that it can be recommended without further treatment.

Sensibility and Sensibilization to Light Rays—The title of this serial article by A. C. Guillaume has a practical sound, but the author merely deals with a theoretical problem of pure physics. In his conclusions he considers the transformation of actinic rays after these have been temporarily absorbed by the skin—for without absorption, there can be no physiological or therapeutical action. Incidentally he states that there is no inborn sensitiveness to these rays and those who show sensitiveness have become sensitized by the rays themselves. There are a number of transformations of energy possible such as (1) change in the wave length and production of caloric rays, (2) biochemical reactions, and (3) ordinary electric energy, as shown by the behavior of the electroscope. There is also the development of fluorescence, but this phenomenon stands in some relationship to failure of absorption. Collectively all of these transformations sum up as modalities of the disintegration of actinic light. As to how these transformations are made possible in a skin not originally sensitive to light the author poses the existence of what he terms a colorant which exerts a sort of catalytic action and sensibilizes the skin. He makes a comparison here with the solutions used by photographers. If fluorescence develops, the presence of an absorbent substance in the sensitive system will do away with it—*Le Bulletin Medical* 20, 21 and 22, 1926.

The Abuse of Rest in Cardiac Therapy—It is firmly established that rest is a valuable measure in the treatment of heart disease, and William D. Reid (*Boston Medical and Surgical Journal*, June 3, 1926, cxciv, 22) freely admits that he frequently resorts to it. He contends, however, that it is too frequently and too strictly applied in cardiac therapy. The presence of heart failure (broken compensation) of a sufficient degree or that of heart infection in an active stage is perhaps the chief indication for rest. Heart failure of moderate severity, particularly if not persist-

ent, is not, of course, incompatible with being up and about. In most cases of cardiovascular syphilis the patient does just as well if allowed moderate activity provided suitable antisiphilitic therapy is administered. In rheumatic heart disease, after the disappearance of signs of activity of the disease, the author finds no convincing evidence that prolonged rest in bed (for many months) accomplishes anything better than does gradual resumption of activity a short time (one to four weeks) after the disappearance of the acute stage of the disease. Unintended harmful results of rest are (1) Physical—the difficulty of getting elderly patients out of bed again, the danger of hypostatic pneumonia and loss of muscle tone, (2) psychic—the danger that condemning the patient to idleness may perpetuate a neurotic tendency and result in a fixation of the idea of invalidism, (3) economic. Finally, suitable exercise is part of good hygiene; its benefits should not be denied to individuals with diseased hearts.

What Is Sport Heart?—H. Herxheimer, of Berlin, asks what is the exact status of the so-called athletic heart. Three theories have been proposed: (1) that it is a simple hypertrophy from overuse, (2) that it is an acute passive dilatation, and finally (3) that it is something sui generis known as "active dilatation." The author himself has studied the matter exhaustively in a number of subjects and concludes that when the heart is unduly overburdened it responds by an hypertrophy which is sometimes not out of proportion to the simultaneous development of the skeletal structures, but in other cases is much more pronounced. In such cases the volume of the heart is increased to all tests and the author finds the enlargement a perfect hypertrophy in all of its measurements. The author found further that in a seasoned athlete in the pink of condition the heart undergoes a sort of relaxation in which hypertrophy may or may not coexist. He demonstrates that an acute passive dilatation of these hearts is a physical impossibility. Such a heart would be quite unable to empty itself by systolic contraction. In reply to the claim that after a period of passive dilatation the heart may undergo hypertrophy, the author replies that such delayed hypertrophy is unheard of and that hypertrophy must occur at once or not at all. In regard to the so-called "active dilatation," in which the heart is said to hypertrophy with increase in its capacity, Herxheimer states that the term is a misnomer. What others have called "active dilatation" he himself has termed relaxation of the muscle. As already stated he recognizes the existence of this condition—*Klinsche Wochenschrift*, April 23, 1926.

Retrograde Capillary Pulsations in Heart Failure—A retrograde capillary pulsation, one coming from the venules back into the capillaries, seems not thus far to have been described. Such a case has been studied by C S Danzer (*American Journal of the Medical Sciences*, May, 1926, cxxi, 5) in a patient suffering from mitral stenosis, probably associated with tricuspid insufficiency. The capillaries of the skin were visualized by the Lombard-Müller-Weiss method. By this technique the subpapillary venous plexus was made very prominent. The venous portions of the capillaries were especially dilated. In one capillary under observation the corpuscles altered their course, taking first the normal then the reversed direction. In a number of other capillaries there was a periodic acceleration and slowing of the blood stream. There were phases when the corpuscles coming from the arterial limbs of the capillaries collided with those regurgitated back from the venules into the capillaries. This was obviously the result of venous stasis and regurgitation attending tricuspid insufficiency. Such a collision of corpuscles in the venous limbs of the capillaries is never seen in health. These findings prove the existence of back pressure in the venous system. This fact assumes great importance in the differentiation between circulatory failure due to back pressure (venous stasis, right-sided cardiac failure) and that due to diminished vis a tergo (left-sided heart failure). In the latter case no such signs could be present. The pressure in the capillaries was determined by the Danzer-Hooker method with the microcapillary tonometer. As the capillaries were compressed the first stage, or beaded flow, was followed by the fourth stage, reversion of the blood stream, both of these were intermittent instead of continuous. The fact that both stages were periodic is the essential pathological feature of the observation. It is probable that a retrograde capillary pulse is sufficiently characteristic to be used diagnostically in obscure cases of tricuspid leakage.

Serum Treatment of Tetanus—Jonathan M Wainwright (*Archives of Surgery*, May, 1926, xii, 5) finds from a study of British and American statistics that tetanus is rare in the ordinary type of industrial wounds, it does not occur sufficiently often to warrant urging routine prophylactic injections in all industrial wounds. We must, however, accept the possibility of tetanus arising in the most unexpected cases and rely only on the possibility of improved curative treatment. Although the war proved beyond question the value of prophylactic injections, there has been considerable doubt as to whether antitetanus serum has any real curative value after symptoms are established. This pessimism is largely due to two factors (1) Antitetanus

serum given intraspinally is harmful and diminishes the chances of recovery, (2) when the serum is administered by less harmful methods it is usually given in doses so small that it cannot be expected to be of any benefit. In 190 cases compiled from the literature, which were treated with 10,000 units intrathecally in a single dose, the mortality was 59.5 per cent, or practically the same as for patients receiving no serum. There is an increase in the death rate when intrathecal injections are added to any other method of treatment. In 90 cases compiled from the literature or reported directly to the author, when 30,000 or more units were used intravenously the first day of treatment, the mortality was 32 per cent. If this dose is not completed till the end of seventy-two hours, the mortality rate rises rapidly, though even so it does not reach the hospital average. Given by vein in doses from 30,000 to 50,000 units or more, according to the severity of the symptoms and the time since onset, it will divide the present mortality rate by two or three, or more. The efficiency of this dose will depend upon the promptness with which it is given. If the initial dose has to be repeated it should be of approximately the same size and by vein only. In the last days of convalescence intramuscular injections are allowable. The best sedative is chlorbutanol, in a dose of 30 grains (1.95 gm) dissolved in hot whiskey by mouth, or 75 grains (4.87 gm) in hot olive oil by rectum, repeated sufficiently often to keep the patient relaxed and drowsy until the danger is past.

Influenza in Infants and Children—During a recent epidemic of influenza which largely attacked infants and children, James Burnet (*Archives of Pediatrics*, April, 1926, xlii, 4) had unique opportunities for making observations. He found the incubation period short, in one or two instances twenty-four hours, the temperature high in the majority of cases, prostration and apathy and lethargy well marked. Three clinical types of the disease were distinguished. (1) *A catarrhal type* was the commonest, it was characterized by running from the nose, a dry, hard cough, which was extremely irritating, and in some instances vomiting and diarrhea. In older children headache was complained of. This type more than any other had a tendency to develop otitis media. (2) *A cerebral type* was noted in which the symptoms were meningeal, there being twitching, drowsiness, and stupor, with high temperature (105°), and in two cases convulsions. (3) *A colic type* showed symptoms quite out of the ordinary. The child complained of colicky pain in the region of the umbilicus, which gradually became more intense.

The abdomen was definitely tender in the center, but peripherally and in the flanks there was no pain. Vomiting and diarrhea did not occur. The author explains this pain as due to the effect of the influenza on the intestinal muscles, leading to spasm and consequent pain. These cases also presented the characteristic dry, irritative cough. In the treatment of influenza in early life, the patient should be kept warm in bed during the attack, and for some days after the temperature has become normal. A febrifuge should be administered with small doses of wine of ipecac. The diet should consist of milk, soups, and later milk puddings, fish, and chicken. During convalescence cod-liver oil, nux vomica, and iron should be given. In the colic cases, warm linseed poultices are useful in relieving the pain. Steps should be taken to prevent middle-ear infection.

The Reticulated Red Cells—Their Clinical Significance.—In the opinion of William Dameshek (*Boston Medical and Surgical Journal*, April 29, 1926, cxciv, 17) the significance of the reticulated cells, though more or less realized, has not yet been fully sensed. At the Blood Laboratory and Clinic of the Boston City Hospital routine studies of the reticulated count have been made in all cases since 1919. The method employed consists in placing a drop of blood on a cover slip which is inverted on a slide containing at one end a dried drop of cresyl blue, 0.3 per cent in alcohol solution. The drop of blood and dye are allowed to mix for three or four minutes. Under high dry power or oil-immersion, those cells which are seen to contain within their cytoplasm granules, rods, or network are called reticulated, and their number is counted. In 50 cases of pernicious anemia followed over periods sufficiently long for intelligent observation, the reticulated count rose in practically all cases to a point above 6 per cent before a remission. Relapse, usually death, followed always in the wake of a continued low count. Transfusion and splenectomy are futile in the presence of a continued low count. In practically all cases there was some rise, however slight, following transfusion. Occasionally a reticulated count is seen to rise sharply, presaging a remission, and then because clinically the patient seemed in jeopardy, transfusion is done. The remission which occurs naturally has then been ascribed to the transfusion, when undoubtedly it would have come without it. A study of aplastic anemia with its continued low reticulate count, purpura hemorrhagica which shows an interesting parallel between platelets and red cell regeneration, congenital hemolytic anemia, the anemias of pregnancy, and the secondary anemias, indicates that the reticulate count of the red cells is a true index of the

amount of bone-marrow activity—a better one than nucleation of red cells, polychromatophilia, or stippling. Before and at the beginning of any remission or permanent rise in red count the reticulate count surpasses 6 per cent, as the culmination of the rise is reached it gradually falls to normal (0.5 to 1 per cent). With bone-marrow aplasia, the reticulate count is extremely low, practically nil. The relapse in pernicious anemia is closely related or at least extremely similar to aplastic anemia, which, with its evident bone-marrow failure, has an almost absent reticulate count. Platelet regeneration and aplasia are apparently closely related to red cell growth, for in purpura hemorrhagica the reticulate count goes up before recovery, but remains low in cases of impending death from hemorrhages. In the field of diagnosis, marked reticulosis in congenital hemolytic anemia is a pathognomonic point differentiating that disease from all other anemias with large spleens. In the primary type of anemia of pregnancy, the reticulate count behaves exactly as in pernicious anemia. In the leucemias and diseases of lymphoid origin, the reticulate count may be slightly elevated, but without relation to the course or scope of the disease.

Prophylaxis of Measles.—M. Meissner writes of results obtained from the injection of Degwitz's convalescent measles serum in a child sanitarium. The serum used in the sanitarium in question, which is in Chemnitz, was not a commercial one but was prepared extemporaneously in the Chemnitz General Hospital. The population of the institution is in the vicinity of 200, all of the children being sickly, with symptoms pointing especially to scrofula and tuberculosis. For measles to gain entrance here would mean, as it has in the past, a disaster. The latest batch of admissions comprised thirteen children, and according to custom all were segregated for examination before they were allowed to mingle with the other inmates. Of the 13 one was found to be in full measles, and the others had been in its company for about two hours. Five of the 12 were known to have had measles, while the other 7 were not known to have had the disease. Each one of the 7 received one unit of the convalescent serum. No new case developed and after 14 days the 12 new patients were allowed to mingle with the other residents, and again there was no development of the disease. Of the seven immunized one developed a late urticarial outbreak—on the fifth day after injection—which was attributed to the serum and which vanished in a day or two.—*Medizinische Klinik*, April 23, 1926.

NEWS NOTES

TESTIMONIAL DINNER TO DR SHAW

The Testimonial Dinner to Dr Henry L. K. Shaw, which was voted at the last meeting of the Council, found a happy conclusion at the University Club, New York City, when forty-five men sat around the board and congratulated the Committee on Legislation, of which Dr Shaw is Chairman, on the successful passage of the Medical Practice Act.

Dr Augustus Downing was an honored guest as were Senator Webb, Hon George W Whiteside, Wendell C Phillips, Health Commissioner Louis I Harris, Mr Lloyd P Stryker, Ex-Presidents Van Etten, Jones, Wightman and a host of friends who had labored long years to bring about the passage of a Medical Practice Act.

Dr Dougherty read a telegram of congratulations from State Commissioner of Health Matthias Nicoll, and messages were also read from Dr Trick of Buffalo, Dr Rooney of Albany, Doctors Cady, Kevin, Chittenden, and Lytle.

Dr George Fisher, who presided, humorously stated what probably is a fact—"The Medical Practice Act represents in principle as great an event as when the Lord gave Moses the Ten Commandments."

Dr Van Etten reviewed the progress of the State Society during the past year, emphasizing the able scientific programs which Dr MacFarlane had secured. These reached a high point of efficiency in the syphilis exhibit. He mentioned also the educational programs, given with the whole-hearted support of Dr Nicoll, State Health Commissioner.

The Medical Practice Act was passed under Dr Shaw's leadership. This was a most able achievement. Too much praise could not be given to the lay organizations, such as the State Charities Aid Association, who did yeoman service in awakening a public conscience to the justice and need of the bill. It was a bill for the protection of the people and not the medical profession. Dr Phillips spoke truly when he said that it was one of the most notable medical achievements in a decade. It was first, last, and always a Public Health Act and should be the basis for other States to formulate the necessary law to drive out quacks and charlatans.

Dr John Jennings, who took an active interest as one of the Committee who drew up the Act, felt it was a notable event and expressed his congratulations to Dr Shaw for its passage.

Hon George W Whiteside, our former Counsel, was particularly fortunate in his congratulations. The bill has been drawn and revised times

without number by Mr Whiteside. Each administration had added something worth while. The background had been strengthened by uniting our Departments of Health and Education. Then the Lay Organizations joined, and a united front resulted. From then on the Bill was not the doctors' bill, but a bill for the protection of the public health.

Mr Whiteside paid a just tribute to Dr James Vander Veer, whose tireless energy at Albany, as former Chairman of the Legislative Committee, made the machinery of this office effective.

Dr Louis I Harris, Health Commissioner of New York, added most valuable advice when he stated that the passage of this act was a solemn obligation upon the medical profession—one which we should not take too lightly. Our attitude should be conciliatory, and the profession should be unified. Lay bodies would stand behind the profession as long as we do a public service. The medical profession should be impersonal and have a solemn sense of its duty. It owes Dr Downing an obligation, and should support him in time of stress. Public health commands the community. The passage of this act is the beginning of a colossal job.

Dr James Vander Veer spoke modestly of his past tribulations, but emphasized the able work of his lieutenant, Dr Joseph Lawrence, our Executive Officer, who quietly carried out Dr Shaw's policy in unifying every available lay body in support of the Bill. He felt that doctors should only promulgate the right ideas—laws which were as honest in their intent as their oath to practice. People always follow an honest doctor.

Mr Stryker, Counsel of the State Society, said that in a period of reconstruction a unity of action was imperative. There would be men who through a misunderstanding might cause temporary embarrassment, but the time would come, and that shortly, when the basic value of the new law would be appreciated, and then everybody would help.

Dr Wendell C Phillips, President of the American Medical Association, said he was genuinely proud of New York State, not because he was born in St Lawrence County, but because New York was helping the whole country when it took the lead in trying to set a standard medical practice act. He said that a valuable section in that law was the inclusion of a Grievance Committee, and that the men who were to be selected should have a just mental angle, coupled with a fearless administration of the office.

Dr Downing congratulated the Society on a unity of action which had secured the passage of the Bill. He felt that his part in it was all in a day's work. He felt glad he had accomplished something, there was nothing to exalt one, it was a task which concerned the health of the people. This Bill was the best one passed by any state as far as he knew. It was not perfect, but was a good beginning. Minnesota was trying to put one over, Rhode Island the same, Maine sent congratulations—Texas, Illinois, all wanted to get in line. We probably had planted better than we knew. Physicians were not detectives. Malpractice was a crime against the people of the State, not against the medical profession. There need be no worry about the enforcement of the law, it would come surely and positively.

Dr Downing added a word for fair play "Don't hit a man when he is down." He might have added a "down and outer," once convinced sometimes makes the best kind of an enthusiast.

Dr Shaw's reply to all the kind things which were said about him was what might have been

expected. He was deeply impressed by an occasion which had brought men from all parts of the State to do honor to the passage of the medical practice act. As far as he was concerned he felt that most of it was undeserved. He wanted to emphasize the work done by Dr Lawrence, who proved his worth by uniting the lay bodies in support of the Bill. The background had been well laid by his predecessors, and the injection of a few new ideas, added to the work already done, had accomplished the dream of a decade.

The writer, who was present, can recall no occasion of a dinner given over to State affairs when so genial a spirit was present. It only emphasized the value which gatherings of this kind may attain. There was neither "boast of chivalry nor pomp of power," but a spirit of comradeship and a singleness of purpose for the best interests of the profession.

Dr Kopetzky, as Chairman of the Testimonial Dinner Committee, is to be congratulated on its success.

CLINTON COUNTY MEDICAL SOCIETY

The semi-annual meeting of the Clinton County Medical Society was held on June 15, 1926, and was preceded by a luncheon at the Witherill Hotel.

Dr T. A. Rogers was authorized to formulate plans for the formation of an auxiliary society to be composed of medical and laymen, and to present same to this Society at a future meeting.

The Committee on Public Health and Medical Education reported through the secretary that they had arranged a course of post-graduate lectures in Obstetrics through the State Society Committee, and that such course had been given with considerable success.

The Society invited the Fourth District Branch to hold its annual meeting at Plattsburgh.

The scientific program was as follows:

1. The X-Ray in Diagnosis and Treatment by Dr. E. S. McDowell.

2. The Importance of Early Diagnosis in Gastric Conditions, by Dr. I. G. Barton, Jr.

These papers were amplified by the exhibition of X-Ray plates.

3. Diphtheria Prevention, by Dr. Herman Senftner.

Discussed by Drs. Burdick and Schiff.

Following this paper, the following resolution was carried by the Society:

In view of the occurrence of cases of diphtheria from time to time in Clinton County, in spite of improved methods of treatment and better enforcement of health regulations, and further

Believing that the value of toxin anti-toxin as a preventive measure against diphtheria has been fully demonstrated

Resolved, That the Clinton County Medical Society endorses the state wide campaign for the eradication of diphtheria.

We urge parents to have all children under ten years of age protected by toxin anti-toxin injections, and particularly to have this done when possible before the child reaches the age of one year.

INFORMATION CARD OF A M A DIRECTORY

During the month of June, every physician in the State should have received a Directory information card. Every one is urged to fill out and return the stamped card regardless as to whether he or she has changed their residence or office address. This information will be used in compiling the Tenth Edition of the American Medical Directory, now under revision in the Biographical Department of the

Association. The Directory is one of the altruistic efforts of the Association and is published in the interest of the Medical profession which means ultimately in the interest of the public. It is a book of dependable data concerning the physicians and hospitals in the United States and Canada.

AMERICAN MEDICAL ASSOCIATION

June 15, 1926

THE DAILY PRESS

AUTOMOBILE KILLINGS

Civilization brings its own peculiar dangers to life and health, and the automobile has displaced some of the common contagious diseases as a cause of death

The New York Tribune for June 14, contains an article with the following headlines

"22,500 killed by autos in 1925, 675,000 hurt"

Cartoon from the New York Herald Tribune June 21 1926
Another crop where the supply exceeds the demand

The article is based on the reports of the National Bureau of Casualty and Surety Underwriters, and of the statistics committee of the National Safety Council. This indicates that about six persons in every 1,000 of population will be killed or injured in automobile accidents during the present year.

It is disconcerting to read that the number of automobile accidents is increasing. The article says

"The number of persons killed surpassed a preliminary estimate of 21,000 deaths made by the safety council on the basis of earlier incomplete information. It is possible, the report says, that when complete returns from more cities become

available the number of deaths from automobiles may be increased

'Automobile fatalities excluding collisions with street cars and railroad trains, increased from 17,600 in 1924 to 19,800 in 1925, the report continues. Automobile grade-crossing fatalities increased from 1,668 in 1924 to 1,784 in 1925

"The automobile death rate per 100,000 population has increased from 14.9 in 1923 to 15.7 in 1924 and to 17.2 in 1925, the report continues. 'The increase therefore from 1923 to 1924 was 5 per cent, while the increase from 1924 to 1925 was nearly 10 per cent. Automobile fatalities are, therefore not only increasing in number, but the rate at which they are increasing also is going up.

"Registrations increased from 17,591,981 in 1924 to 19,954,347 in 1925. Fatality rates on the basis of registration have been decreasing for several years it is said, but there was virtually no decrease this year.

During 1925 it is estimated that 6,300 children under fifteen years of age were killed in automobile accidents compared with 6,090 in 1924. The rate of deaths to children under fifteen increased only about 3½ per cent over 1924, however, while the fatalities among grown-ups increased about 14 per cent. This fact seems to indicate, the report says, that safety education in the schools is having its effect.

"Certain cities which have carried out intensive safety programs have noticeably decreased their automobile fatalities, showing that the situation can be controlled, the report continues."

The proportion of automobile fatalities in New York State is about the same as it is in the rest of the nation. The vital statistics reports of New York State for 1924 show that 1,987 persons were killed by automobiles in the State. This number of deaths exceeds the number caused by diphtheria, typhoid fever, and scarlet fever.

The cause of automobile accidents in a series is discussed by the New York Sun on March 5, and is shown in the following table

Skidding	36 per cent
Failure to observe the right of way	28 " "
Exceeding speed limit	15 " "
Cutting left corner	6 " "
Driving off roadway	6 " "
Driving on wrong side of road	6 " "

The proportion of the causes of injury to pedestrians were

Jay walking	25 per cent
Crossing streets against signals	7 " "
Injured at street intersections	30 " "

Dr Downing congratulated the Society on a unity of action which had secured the passage of the Bill. He felt that his part in it was all in a day's work. He felt glad he had accomplished something, there was nothing to exalt one, it was a task which concerned the health of the people. This Bill was the best one passed by any state as far as he knew. It was not perfect, but was a good beginning. Minnesota was trying to put one over, Rhode Island the same, Maine sent congratulations—Texas, Illinois, all wanted to get in line. We probably had planted better than we knew. Physicians were not detectives. Malpractice was a crime against the people of the State, not against the medical profession. There need be no worry about the enforcement of the law, it would come surely and positively.

Dr Downing added a word for fair play. "Don't hit a man when he is down." He might have added a "down and outer," once convinced sometimes makes the best kind of an enthusiast.

Dr Shaw's reply to all the kind things which were said about him was what might have been

expected. He was deeply impressed by an occasion which had brought men from all parts of the State to do honor to the passage of the medical practice act. As far as he was concerned he felt that most of it was undeserved. He wanted to emphasize the work done by Dr Lawrence, who proved his worth by uniting the lay bodies in support of the Bill. BOOK REVIEWS

HEADACHE, ITS CAUSES AND TREATMENT By Dr THOMAS F. REILLY, Attending Physician Bellevue and Allied Hospitals, Fordham Division, and at St. Vincents Hospital. P. Blakiston's Son & Company, Philadelphia, 1926 Price, \$3.00

Headache is one of the commonest symptoms encountered in medical practice. Any attempt to clarify the mystery that surrounds this symptom deserves commendation. The author presents the characteristics of headache as it occurs as a part of the symptomatology of a great many diseases.

The book presents on careful study the impression that it was hurriedly written, and a new revision will be of much more value than this first production, although the present edition is of considerable value. An illustration of the lack of a critical review of its contents is to be found under Simple Goiter. It is a well established fact that there are no constitutional symptoms produced by simple goiter, and symptoms occurring in such patients are the result of some other diseases and not a by-product of the goiter. It is rather uncomplimentary to speak of patients with goiter as "an exceedingly unstable lot."

The book is of value, and we take great pleasure in recommending it to anyone interested in headache, which surely ought to interest every practitioner of medicine.

J. ARTHUR BUCHANAN

LISTER AND THE LIGATURE. A Landmark in the History of Modern Surgery. Compiled by the Research Readers of the Scientific Department. Octavo of 89 pages, with illustrations. New Brunswick, N. J., Johnson & Johnson, 1925

In this little book the research workers of the scientific department of Johnson and Johnson have collected the facts relating to the re-introduction of the absorbable ligature. They have pointed out the important part that Lister and Listerism have played in rendering generally available this necessary surgical material quoting, at length, from publications in which his writings appeared. The illustrations are of Lister himself, and of some drawings made by him.

These few pages leave one deeply impressed by the genius for research and investigation of Sir Joseph Lister, and make interesting and instructive reading for the student of surgical history.

J. R.

THE STOMACH AND UPPER ALIMENTARY CANAL IN HEALTH AND DISEASE. By T. IZON BENNETT M.D., (London), M.R.C.P. Assistant Physician to the Middlesex Hospital Physician to the Royal National Orthopaedic Hospital etc. William Wood & Company, New York, 1925 Price, \$6.00

This book written by an English gastroenterologist can be recommended as one of the best treatises on the subject of gastroenterology yet published. The writer has evidently had a vast experience in treating the various infections of the gastrointestinal tract by eradication of local infections and the book is therefore the first to give the proper amount of space to this all-important factor in the causation and treatment of these infections. His recommendations for treatment are safe and sane, and are not bound down by ancient tradition, as are most of the therapeutic directions in text-books on this subject. The chapters on physiology and on general examination of patients are well worth careful study. The illustrations and tables are well-chosen. The so-called "functional disorders" are dismissed with the

scant attention they deserve. The book is one that the general practitioner as well as the specialist should own and study.

A.

LIGHT AND HEALTH. A Discussion of Light and Other Radiations in Relation to Life and to Health. By M. LUCKIESH and A. J. PACINI. Octavo of 302 pages, illustrated. Baltimore, Williams and Wilkins Company, 1926 Cloth, \$5.00

Though not strictly a medical work, this book presents an excellent exposition of the far reaching relationship of light and health. There are chapters of particular interest on light and its effects on the various body structures, their development and maintenance in normal function. A chapter on light and infection presents some remarkable aspects of phototherapy in the handling of such conditions. The effects of light upon hygiene, the senses and upon production in industry, long recognized as existing, are presented in an orderly and comprehensive manner. This book is of inestimable value to all who would treat or prevent abnormal conditions on a truly scientific basis, as it thoroughly presents the present conception of a modality which can no longer be disregarded in therapeutics.

JEROME WEISS

MEMORANDA OF TOXICOLOGY PARTLY BASED ON TANNER'S MEMORANDA OF POISONS. By MAX TRUMPER, B.S., A.M., Formerly Lecturer on Toxicology, Jefferson Medical College, Philadelphia, with introduction and addenda by HENRY LEFFMAN, A.M. M.D., Emeritus Pathologic Chemist Jefferson Hospital, Philadelphia. P. Blakiston's Son & Company, Philadelphia, 1925

This book is a well arranged treatise on the subject of Toxicology. It is compact, scientifically correct in detail and not too voluminous to be of service as a reference in emergency poisoning. The classification of poisons into three groups is practical, namely Corrosives Irritants and Neurotics, the latter being further subdivided.

A treatise of this kind should be a part of every physician's library.

FREDERICK SCHROEDER.

NON-SURGICAL TREATMENT OF DISEASES OF THE MOUTH, THROAT, NOSE, EAR AND EYE. By THOMAS H. ODENSEAL, M.D., Otologist, Rhinologist, Laryngologist and Ophthalmologist to the Bernal Hospital Corporation, Beverly Mass. P. Blakiston's Son & Company, Philadelphia, Pa., 1926 Price, \$4.00

In this comparatively small manual the author has attempted to cover the non-surgical treatment of Diseases of the Mouth, Throat, Nose, Ear and Eye. For a task that is at once manifestly formidable, he has accomplished much.

Taken altogether this book is of value as a ready reference for the general practitioner or the beginner in Otolaryngology.

The last twelve chapters of the book are deserving of special mention.

These chapters deal with general subjects of special significance which are all too frequently omitted from some of the even more comprehensive text books.

M. C. M.

ABDOMINAL AND PELVIC SURGERY FOR PRACTITIONERS By RUTHERFORD MORISON Hon. M.A. and D.C.L. Hon. LL.D., M.B. FRCS. 12mo of 212 pages, with illustrations. New York Oxford University Press, 1925 Cloth, \$2.75 (Oxford Medical Publications)

Confused by traffic	11 per cent
View obstructed by umbrellas, bundles, etc	12 " "
Intoxicated	3 " "

Back of the causes enumerated in these tables is the mental attitude of both the drivers of the cars and of the pedestrians

Is it possible to detect the type of mind which is liable to lead to accidents? Psychologists say that it is

Everybody knows that absent-mindedness leads to accident. A man with a "one track" mind is likely to forget the road and his steering wheel while he is absorbed in his literary or scientific thoughts

The reaction of the brain is also to be considered. Some people react quickly to stimuli and others only slowly. One-tenth of a second is a fast reaction time in which to respond to a signal. Half a second is slow, and will lead to accidents

The reaction time is also slowed by fatigue. Many a tired doctor has driven his auto through the side of his garage because his brain was too fatigued to send the stop order to his foot promptly

The newspapers have recently carried a number of articles on psychological tests for auto drivers. An unusually slow reaction time will be disclosed with great precision, and other factors may be determined

The New York Tribune for March 11 describes the plans of the Yellow Taxi Corporation for testing its drivers, and says

"Drivers of the Yellow Taxi Corporation soon are to undergo psychological tests to keep the streets from those who, through lack of mental celerity, add to the toll of street accidents. A clinic for this work now is being established in the company's offices in 514 East Twenty-third Street, and will be ready in May or June, under the direction of Dr. Bernard Christie Bullen

"Then all applicants for jobs with the Yellow corporation will have to undergo the tests. It is believed they will eliminate 50 per cent of the minor accidents and about 35 per cent of the more serious ones. The tests are partly the work of Professor A. J. Snow, of Northwestern University, and have been developed through special research work in Chicago, where students of Northwestern University were used

"Dr. Bullen said yesterday that the tests will seek to establish three main facts: degree of receptivity, speed of mental reaction, and carelessness. In determining the speed of mental reaction, Dr. Bullen will try to learn the speed of

awareness of change in traffic signals. The results will be recorded mechanically and will be considered infallible

"The great hazard in taxicab operation," said Dr. Bullen, "is the smart aleck, know-it-all type. In our mechanical tests this man can escape us. He is too quick for these tests. In a classroom, under the eyes of an examiner he shifts gears, backs, starts and does everything else that he is told to do correctly. But after a few weeks or months on the street his know-it-allness develops into sheer recklessness, and there is trouble. A well developed medico-psychological tests should eliminate this type at the start

"Another dangerous type is the superlatively cautious man. Give this type a test for his speed in reaction, and you have him stopped at once"

The New York Tribune of February 20, prints a letter from Paul O. Komara, of the National Committee for mental hygiene, which explains the scientific basis for the psychological tests. It says

"The recent announcement of the Committee on Causes of Accidents of Secretary Hoover's National Conference on Street and Highway Safety, that mental examinations would be recommended for reckless automobile drivers furnishes another illustration of the usefulness of a diagnostic agency which has developed apace with the growth of the mental hygiene movement the psychiatric clinic

"The psychiatric clinic, in which the psychiatrist, the psychologist and the psychiatric social worker combine their resources, is the laboratory par excellence for the investigation of the human personality, and such questions as the mental age, required in persons desiring to qualify as safe drivers of motor vehicles, the presence or absence of mental disease, whose symptoms are not easily discernible, emotional disabilities, mental attitudes, etc., offer a fertile field of inquiry that should yield results having a very definite bearing upon the practical solution of this serious problem. Any campaign which aims to reduce accidents cannot reach its highest degree of success unless the 'human element' or 'mental element' is taken into account and the psychiatric clinic deals primarily with that element"

The psychologists of the United States developed a series of mental tests to be applied to soldiers as their peculiar contribution toward winning the war. The great success of the tests arouses confidence that the psychologists will devise equally practical tests that will detect the auto drivers who are likely to have accidents

THE MENTAL HEALTH OF SCHOOL CHILDREN*

By WILLIAM A. HOWE, MD, ALBANY, N Y

State Medical Inspector of Schools

THE mental health of school children is one of the biggest, the most promising in its possible future results, and yet the most seriously neglected of health problems of the present day. The rapidity with which nervous disorders are increasing among school children and the continued failure by physicians, educational authorities and parents to give proper medical, educational and parental attention to them, amaze and alarm students of child health. During the past ten years the number of children reported in one year to the Medical Inspection Bureau suffering with nervous disorders increased 3,196 or 169%. This, as you will note, gives an annual increase of 16.9%. These figures, which I appreciate are not accurate, except in clearly indicating the rapid increase in the incidence of mental illness, do not include the mentally defectives, of whom we have many thousands in our public schools, ranging from low imbeciles to high morons. Our reports received do not fully indicate the actual conditions existing. Thousands of the minor cases are not even recognized and many others fairly well established in their mental deviations are not included in the reports. Even more serious than the failure to recognize and report these cases, is the almost criminal neglect or failure to give to them the preventive and correctional treatment so vital to their mental health, their happiness, their success or failure in life.

Our State Hospital Commission advises us that during the past ten years, the same period covered by our school reports there has been an increase of 181% or of 18% annually in the number of persons admitted to institutions for mental diseases. These figures, like those for the schools, do not include the mentally defective. These school and hospital statistics to which many others could easily be added, furnish conclusive evidence of the extensive and increasing prevalence of mental illness and the urgent need for action. In this,

as in most fields of modern medicine, the greatest opportunity to accomplish practical results is found in preventive measures.

The problem is fundamentally a medical one. To deal successfully with it medical knowledge and direction are indispensable. The physician is the natural leader in the movement. Let us hope that he will not lose his opportunity to lead.

ETIOLOGICAL FACTORS IN THE MENTAL HEALTH OF CHILDREN

Many and varied causal factors influence the mental health of children. We find them within the child, inherited or acquired, within the parents, within the home, within the school, within the companionship, within the community and in many other places. Within the child they may be due to an inherited predisposition to mental instability, or to some physical defect, said to be present in 85% of all cases, or to some faulty elimination, intestinal, nephritic or otherwise, or to some focal infection in abscessed teeth, diseased tonsils or elsewhere, or to some deficient glandular action, endocrine or otherwise, or to unrestrained emotional conditions, or to fatigue, mental or physical, often not recognized, appreciated or properly treated, or to any one of many other causes.

By parents we find influences, good or bad, exerted before and after birth. Both prenatal and post-natal influences as exerted by parents are potential factors in the ultimate success or failure of the child. Both require careful consideration and wise direction. Those of prenatal origin, embracing combined maternal and paternal force, are the strongest and the most enduring, lasting in many instances throughout life. Those of post-natal development present a greater variety, are often more complex in character, seem more difficult to control, though of parental origin, and may produce most disastrous results.

It is a wise parent indeed who carefully

* Read before the State Medical Society March 31, 1926

Quite a number of monographs have appeared of late on the acute surgical diseases of the abdomen and the reviewer had occasion to comment on a number of them in these columns. The present little volume, however, exceeds in interest and merit most of its predecessors. Surgical technique and the various operative procedures are left out entirely. Its contents are limited to a recital of the author's personal experiences with practically every possible abdominal condition extending over a considerable period of time in an extensive surgical practice. Special stress is laid upon diagnosis emphasizing that if the condition is surgical the patient should be submitted to operation at the earliest possible opportunity.

It is a most practical book. Theories and speculative dissertations are conspicuous by their absence. Not a word about complex laboratory procedures, except for an occasional reference to the ordinary blood count or urine examination. It is the clinical side that is dwelt upon and the conclusions that may be drawn from a careful examination of the patient with the particular purpose in view to operate if the condition is surgical.

A most excellent book to have on one's desk and to refer to it frequently in order to refresh one's memory and also to recall some personal experiences that might have terminated more favorably if recognized and treated properly.

HERMAN SHANN

OPHTHERAPIE ENDOCRINIENNE. Les Bases Physiologiques, les Syndromes, la Posologie de l'Opothérapie par les Glandes à Sécrétions Internes. Par GUY LAROCHE. Octavo of 256 pages. Paris, Masson & Cie, 1925. Paper, 12 francs.

The most outstanding contributions to medicine made in the last few years have been in the study of the endocrine glands and the successful extraction of their active principles. No one today questions the important function that these glands play in maintaining the physiologic development of the individual and we have all observed the serious and obvious changes that occur when the glands have become diseased and their secretions diminished, increased or perverted.

The author has succeeded in condensing into a small volume of 256 pages and 17 figures a review of the entire field. Each known endocrine gland is described, the literature reviewed and its function considered in detail. Those syndromes that result from abnormal or deficient secretions are fully described, those clinical and biological tests of recognized value discussed and the indications and contra-indications for treatment are outlined. The various methods used in isolating or extracting the active principles are fully described and details are given as to dosage and mode of administration.

H. M. FEINBLATT

AN EPOCH IN LIFE INSURANCE. A Third of a Century of Achievement. Thirty-three Years of Administration of the Metropolitan Life Insurance Company. 2nd Edition. Octavo of 306 pages. New York, The Company, 1924.

A review of sixty years business in life insurance, especially the last thirty-three. This is a fascinating story of early struggles and severe competition for a quarter of a century and then a rapid and marvelous growth to the proud position of leader of them all. Especially interesting are the chapters showing the reasons for mutualization, the need and provision for standard insurance, disability and indemnity clauses, etc. The chapters on welfare work for policy holders and employees, investments and war work give an insight of some of the many lines of work a large insurance company must follow.

L. S.

ABDOMINAL OPERATIONS. By Sir BERKELEY MOYNIHAM. 4th Edition, revised. Two octavo volumes totaling 1217 pages, with 470 illustrations, 10 in colors. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$20.00.

A fourth edition of this classic book is welcomed by American surgeons, particularly by those who remember the sensation that was caused by its first appearance. It was a good book, presenting, as it did, the interesting spectacle of an Englishman taking surgical America seriously without losing his own self-respect.

It is a good book and it has the same virtue still. It is essentially a study of standard method in abdominal surgery from a British surgeon informed by American travel. Sir Berkeley Moynihan, the most American of British surgeons, could almost pass as the most British of Americans.

He has grasped much of the American emphasis on method perhaps a little too much, more, one would say than our real leaders betray and yet not too much for England which needs just that stress, nor for the average surgeon anywhere and he has injected a good deal, quite a little, perhaps a little too little of the sturdy British common sense that we here in America need.

Shall we say that to this synthesis he adds that mysterious charm that he himself owes to the race that gave him birth?

The last edition of this book was published just before the war and what the author, in his preface, describes as a very drastic revision has taken place. Two chapters have been deleted and several new chapters among them one on Surgical Technique, which in its simplicity and its essential completeness well repays study, have been added.

A chapter on the Complications and Sequels of Abdominal Operations is equally valuable.

The chapter on Acute Peritonitis is missing which is a loss. The time is ripe for a review of that subject but it will require more bacteriology than is, shall we say, betrayed in the first chapter.

The remaining fifty-four chapters of the book discuss abdominal incisions, gunshot wounds of the abdomen, tuberculous peritonitis, subphrenic abscess, the surgical treatment of visceral prolapse and of intestinal stasis and sections on operations upon the stomach, upon the intestines upon the liver and upon the pancreas and spleen as did the former editions.

It is a great and worthy monument. One looks in vain for novelty or for individual preference, but for sanity and clarity and for simple surgical integrity, it will be hard to find its equal. Once more, may we quote the Preface.

"Surgery today is being practised by too many light-hearted and incompetent surgeons who have neither sought in due service to acquire a mastery of their craft nor have learned from the experience gained by long association in hospital work when an operation should be done when left undone how made safe, how made to fall lightly upon a patient already afflicted it may be by mental no less than by physical distress.

"Of all the temples in the world none is more sacred than the operation theatre. No High Priest nor any acolytes engage in nobler ministrations than do the surgeon and each one of his assistants. Nothing base should dwell in such a temple and—

"As this temple waxes

"The inward service of the mind and soul

"Grows wide within

"Since no joy is greater than that of service in such a sanctuary no responsibility is greater than that which falls daily to our lot"

Bravo, Moynihan!

J. E. J.

sciousness of their inseparable relation to each other so far as life and health are concerned. Let us endeavor to so interpret and utilize the mental and physical findings that the greatest health benefit may accrue to the *whole child*, in doing which we shall make our greatest contribution to individual happiness and to national greatness.

SYMPTOMS OF MENTAL DISTURBANCES AMONG CHILDREN

There is probably no phase of medicine in which we find a wider range or a greater variety of symptoms, often complex in character, than in the mental disturbances of childhood. There is no part of our work as physicians in which a keener discernment is necessary or a better understanding of the interrelations of body conditions and functions is so essential, to clearly understand the relation of one symptom to another and the relation of all of the symptoms to the whole case. It will often be found that each child presents an individual problem in symptomatology. The symptom problems may in fact be quite as numerous as are the cases and often as difficult of understanding. Certain symptoms may predominate and appear of the utmost importance in some cases, while in other instances the same symptoms may be absent or of little or no significance.

All possible symptoms, physical and mental, bearing upon the case must be assembled. The physician must first view them in their entirety, just as he must visualize the whole child.

By a system of exclusion and inclusion such symptoms and conditions as appear most relevant to the case can be selected for intensive consideration. The list from which such selection may be made is often a long one. It may include one or many of the following:

- 1 Over activity—mental or physical
- 2 Under activity—sullenness
- 3 Hypersensitiveness — irritability — excitability
- 4 Obstinacy—stubbornness
- 5 Vicious temper—cruelty
- 6 Tantrums—ill humor
- 7 Exaggerated importance, "Ego"
- 8 Extreme and unnatural jealousy
- 9 Malnutrition—food fads—perverted appetite
- 10 Running away—from school or home
- 11 Stealing
- 12 Lying—habitual
- 13 Sex offenses—precocious sexuality
- 14 Choreic movements
- 15 Convulsions
- 16 Lack of concentration
- 17 Inattention—indifference
- 18 Unnatural behavior, failure to enjoy the natural pleasures of childhood
- 19 Misfit at school and at play

20 Many physical habits such as bed wetting, nail biting, stammering, etc., are also expressions of mental maladjustment.

THE DUTY OF PHYSICIANS IN THE MENTAL HEALTH OF CHILDREN

Most physicians have given little or no attention to the mental health of their childhood clientele.

In far too many instances when an anxious mother seeks advice regarding some nervous or child behavior problem, she is told that "it is of no particular importance and that the child will soon outgrow it." This advice is fortunately true in most cases, and yet the exceptions that prove the rule are far too numerous and often disastrous in their endings. Leading psychiatrists tell us that many of the terminal cases that are today filling our State Hospitals for the insane had their beginning in early childhood.

We are also advised by the same authority that "960,000 children who are today in school will enter a hospital for mental diseases at some period in their lives, if the present rates for first admissions are maintained."

Is not this startling prophecy of the mental wreckage of nearly 1,000,000 school children, a challenge to the medical profession, yes and to our school authorities to organize and to act along preventive lines for the mental salvation of this vast army of boys and girls? It is estimated by those in State Hospital Service and others that in ten years, by proper preventive measures applied to children, the percentage of mental wreckage could be reduced one-half.

This mental hygiene problem as presented to us by those best qualified to judge not only imposes a great responsibility upon the medical profession but offers a wonderful opportunity to render a still greater service to humanity, and to substantially increase our practice. The obligation, as in all great medical problems in time will be met and the services rendered. The time is rapidly approaching when the family physician will fully appreciate that a tantrum may be of even greater significance to the future of the child than a rise of temperature, an accelerated pulse, a carious tooth, a discharging ear, or even a chronic appendix. It is quite as much his duty to the child and to the family to carefully study the various etiological factors that might be responsible for behavior problems, maladjusted or twisted mental cases and to advise and direct proper "mental engineering" as it is to direct the treatment of any other illness of childhood. He must endeavor if possible to find the cases early, as the longer a mental illness has existed the more difficult, as a rule, is its control. He must also appreciate that the more complicated and obscure the causes the more difficult their recognition and solution.

Should he not be fully satisfied with his own judgment, as to diagnosis or treatment, he should

watches the mental and physical health of the expectant mother and who begins early in infancy to lead the child along quiet normal lines of mental development. Normal physical and mental parenthood is conducive to normal physical and mental babyhood. This is the rule to which, of course, there are some exceptions.

The mental atmosphere of the home is reflected in the mental attitude of the child. Within the home we often find many disturbing influences on the mental health of the child. He may not get sufficient sleep, under favorable conditions, without which normal mental health cannot be expected. It must be remembered "that midnight sleep in childhood is far more conducive to mental health than is midnight oil." He may not receive a well balanced diet, the basic necessity of all developments, mental and physical. He may be subject to nervous, irritating, fault finding or other depressing influences of parents, or some other member of the family, in the midst of which he can hardly be expected to escape the contagiousness of such a condition. He may not be happy in his home, so essential in childhood, or receive the encouragement or assistance so often needed and so greatly appreciated by children. He may not understand his parents or they him, and in the confusion of his mind he drifts away to seek advice elsewhere. These and other serious conditions might exist within the home. To properly understand and control them is one of the greatest responsibilities of parenthood.

There are also within the school many factors that materially influence the mental health of children. These may be due to an *overloaded curriculum* imposing on children more subjects, and longer assignments than it is possible for them to carry, or to a *school day so long*, often ten hours or more, as not to afford sufficient time for rest and recreation, or to *attempting to teach* children things they cannot learn and do not like rather than those within their understanding, of greater practical value and more to their liking, or to a *nervous, unsympathetic, irritable teacher*, who fails to understand the psychopathic child or to give him assistance and encouragement when needed, or to *lack of co-operation of school and home*, so essential for the success of both teacher and pupil, or to *bad housing conditions*, such as lighting, heating, ventilation, etc., so necessary for both good physical and mental health, or to *failure of the school authorities* to maintain a system of school medical inspection and health service that will recognize and properly deal with early manifestations of mental disturbances, or to *failure to make children contented and happy* in their school work. A bright, cheerful, happy school environment will do much

for the mental health of children. To make a child feel that he is successful often aids in many maladjustments in school.

The mental health of a child is also largely influenced by his companionship. Children even more than adults are creatures of imitation. For that reason their language and habits furnish to parents a reliable index as to the company they keep. In their early formative and receptive age they are highly susceptible to exposure to good or bad habits, mental, physical, social or otherwise, which to many are just as contagious as measles and more disastrous and lasting in their results. Parents can and should largely select and direct the companionship of their children. To do this and to do it wisely will often prevent many of the mental pitfalls that happen to an innocent and unsuspecting child.

A systematic effort should be made in the medical profession to meet and deal with this, one of the greatest problems in the mental health of childhood.

PHYSICAL AND MENTAL EXAMINATIONS

In the examination of mental hygiene cases it is not sufficient to simply examine as it were the physical side of the child. The examination must embrace the whole child. It must furnish a composite picture of the mental and physical condition of the child. No one simple aspect of the case however complete in itself will suffice. It must rest upon a careful scientific medical investigation and evaluation of the individual case, aided by the teacher whose opinion is worth much, by the parents whose cooperation is indispensable, by the psychologist whose findings are of the utmost importance, by the nurse whose social and other services contribute much to an intelligent understanding of the case, and by others who can often be of material assistance. In making such an examination we must never forget, as so often happens, that the brain is a physiological part of the body. Let us remember that the health and functions of the brain should be as carefully tested and safeguarded as are those of the eyes, ears, nose, digestive tract or any other part of the human mechanism, that in its relation to the rest of the body there is no part of the human anatomy so vitally interdependent or so functionally interrelated as is the brain, that the brain never functions independently, but always in unison with the rest of the body, that neither can function without the other mentally or physically, that both are highly sensitive to and sympathetic with conditions, good or bad, within or without each other, that when we strengthen one we strengthen the other, that to weaken one weakens the other, that to strengthen both strengthens the whole organism, the human body. When we as physicians think of one let us think of both in their completeness. When we examine or deal with either let us do so with a full con-

2 *To the administering educator* that he may realize that education is but another term for *Mental and Physical Development*, that equal consideration may be given to mental and physical growth as to intellectual development

3 *To the class room teacher*, whose knowledge of the child's mental capacity and habits is often more complete and more reliable than is that of the parent, to aid in mental adjustment

4 *To all*, that every person and every agency interested in child welfare may cooperate to insure to childhood, safe, sane and successful direction in mental health

In conclusion let me appeal

1 *To the general practitioner*, of whom we need more, to the family physician whose depleted ranks should be quickly recruited, to the medical

profession whose regrettable lack of interest in and appreciation of health promotion often furnish a sad reflection on medical leadership, to become that for which their training and experience qualify them, the custodians of the mental and physical health of the human family

2 *To the psychiatrist*, by some thought to be the greatest of all medical specialists, to become that for which his intimate knowledge of the interrelation of mind and body qualify him, a more aggressive and helpful leader in the medical field of mental hygiene, especially in its application to childhood

3 *To the psychologist*, whose findings, like those of the bacteriologist are often indispensable to a correct diagnosis of the case, to cooperate with physicians, parents, teachers, nurses, pupils and others, that the best results may be obtained

DOCTORS NEED THE HEALTH VIEWPOINT

By FLORENCE A. SHERMAN, M.D., ALBANY, N. Y.

DURING the past sixteen years, in connection with health educational work, in this and another state, I have had a part in the endeavor to put over a health program through school medical inspection. As I review the work done, I believe that decided progress has been made, but that we have far from accomplished what we should or could, and I have come to the conclusion that one of the main reasons for this has been the lack of the health viewpoint of the doctor (nurse and teacher). There are some 1,600 doctors in this state doing school health work. Some of them are hygienists and some of them are not. Those who are, are putting over a health program. Those who are not are failing to do so. I have reached the conclusion that the doctor must begin his health program with himself. He must endeavor to be physically fit, believe in, embody and radiate health in connection with things he is trying to do. In other words, he must practice what he preaches. I have not always held this viewpoint, but I assure you I do today and it is the basis upon which I am endeavoring to work. I believe the doctor should be a *health teacher in every contact he makes*. It matters not in what special field he is working—public health, school health, private practice—health direction in the colleges, normal schools or industries, the obligation is the same in connection with the wonderful profession which he represents. Teaching boys and girls and men and women health laws how to live wholesomely and health-

fully, in order to measure up to their highest state of efficiency, *should* be the large part of the work of the doctor of today. I believe it is a much *finer* job to show people how to *keep well*, than it is to cure them after they *become sick*. It takes a clever doctor to do this! We must all learn to think in terms of *health* and not in terms of *disease*, and give this message and impression to those with whom we have to do. We must make health contagious through example as far as possible. We are all familiar with what a doctor who is vigorous and vital does for his patient, the psychology of this is far reaching in giving impetus to and in clinching the things we are working for. The program today is a *health program*. *Prevention* not *Cure*. This should be stressed in our Medical Colleges more than it is. Physical, mental and moral fitness are obligations in connection with the high purpose of our profession. I believe we may well ask ourselves these questions:

1 Have I acquired, and am I giving the health viewpoint?

2 Am I physically fit?

3 Am I having and urging period health examinations?

4 Am I practicing what I preach?

5 Am I a good representative of health?

In conclusion, may I express the belief that no matter how earnestly we seek to give others these health measures, the greatest recommendation will be our own observation and embodiment of them.

seek the advice of the psychiatrist or neurologist. He will find, much to his gratification, that most cases of mental disturbances in children, if properly understood and treated, yield far better results than do similar conditions in adult life.

SUGGESTIONS TO THE GENERAL PRACTITIONER OR THE FAMILY PHYSICIAN FOR THE CONSERVATION OF THE MENTAL HEALTH OF CHILDREN

1 Take more professional interest in the mental health of the children of the families of your clientele. To do this also means their general health, for health of body in most cases means health of mind.

2 Establish a consultation relationship with some good psychiatrist or neurologist, and use him as you would a good oculist, a good surgeon or any other good specialist.

3 The New York State Hospital Commission and the New York State Commission for Mental Defectives hold psychiatric clinics throughout the State at regular intervals for diagnostic and consultations purposes. Familiarize yourselves with these clinics and utilize them when necessary for all cases where similar services are not available from other sources. The State Hospitals also welcome your bringing cases to them for consultation and advice.

4 The general practitioner has well been called the *untrained psychiatrist*. He is indeed the nearest we have to the trained psychiatrist, to whom in this work he stands next. By his general medical training and experience, by his familiarity with much of the psychology of the child, of the parents and of the home, by his intimate knowledge of many interrelated factors bearing on the case, he next to the psychiatrist is best equipped to handle many of the more simple and less complicated mental health problems. He in fact with proper training will make the most successful psychiatrist. There is much indeed to encourage the general practitioner to at least make a beginning in this important and fascinating field of *medicine*. To do so would bring to him much of satisfaction in the success with which he would meet, and offer to him an opportunity to render a still further and much needed service to many patients who might otherwise seek advice elsewhere. Let us hope that physicians will take such a deep interest in this special work and do it so well that no occasion or necessity will arise for the development of another specialist, a neuropsychiatrist or a psychopractitioner as it were who thinks he can do the things equally as well or even better than *can be done* by the medical profession.

5 *The general practitioner should realize that both physical and mental health must have the right kind of medical guidance in his community to be successful.*

To successfully deal with mental hygiene cases it is imperative to have the interest and cooperation of the family physician. He must be made

to feel that it is his case and to him must be given credit for its successful management.

He can do much to see that his community is provided with proper medical guidance for mental hygiene cases. Should he be unable to furnish it himself he should if possible see that it is made available and his people should know by whom.

6 Physicians should take an active interest in the educational program in the schools in their community. They should establish and maintain an advisory relationship with the school authorities especially the medical inspector regarding matters of physical and mental health. They should explain to school authorities the significance of mental hygiene, stress its importance and urge its proper recognition and support. They in cooperation with the medical inspector should act as health consultants. The medical inspector should be a contributor to and not a competitor with the family physician. The family physician should be a cooperator with the medical inspector and a contributor to the efficiency of school medical inspection.

ADVANTAGES OF THE GENERAL PRACTITIONER OR FAMILY PHYSICIAN IN MENTAL HYGIENE CASES

The family physician sees the cases earlier when most can be done for them and more often than is possible for the specialist or psychiatrist.

The family physician is more familiar with parental and environmental conditions and can best interpret their relation to the mental status of the child.

He may be acquainted with the prenatal history of the child, often of vital importance to a full understanding of the case.

He, better than anyone else, can get confidential family history and can best deal with the whole family or even the neighborhood as is sometimes necessary.

He, next to the parent, is the most deeply interested in the welfare of the child whose confidence he enjoys, a valuable asset in dealing with such cases.

He best can evaluate the various physical and other findings and make their most effective application to the case.

When psychiatric advice or other assistance is needed, as is often the case, the family physician whose services are always available, is the logical one to select such consultants and is the best fitted to follow the course agreed upon.

CONCLUSIONS

My appeal then is

I To parents, whose responsibility is greatest, to appreciate the vital need of prompt and proper attention to all nervous symptoms of childhood and to lend every possible assistance to the end that their children may receive proper guidance in their mental health problems.

in January, 1925, to be followed in regard to the control of communicable diseases among its students and teaching staff, and one of the University physicians was commissioned as a deputy city health officer to enforce this code, the details of which had been unofficially followed since 1912

This code substitutes for isolation of non-immune student contacts, a period of observation by the University medical advisers. The non-immune contacts are permitted to attend their classes and other gatherings providing they carry out the terms of the observation period. Failure to obey these terms results in the student being isolated in the University Infirmary for the remainder of the observation period. This code applies also to the teaching staff. Co-operation in general is excellent. Last year one of our instructors served a sentence in the Infirmary for failure to comply with the code and the efforts of the full professors in his department failed to secure his release or even mitigation of his sentence. Because of these "teeth" in the code it is readily administered.

The code also specifies the length of quarantine of the communicable diseases, conditions necessary for discharge from quarantine, who shall visit the ill persons, etc.

Under this type of regulation, our non-immune contacts of chickenpox must report to a medical adviser every other day throughout a period of 22 days from the last day of contact. German measles—every 2 days throughout a period of 21 days from last day of contact. Scarlet fever—every day throughout a period of seven days from last day of contact, and so on for the entire group of communicable diseases. The contact is instructed in regard to the early signs and symptoms of the disease to which he has been exposed and told to report to the medical adviser at once should he note any of these signs or symptoms on a day on which he was not required to report.

The noses and throats of our diphtheria contacts are immediately cultured. Last year a case of diphtheria occurred in a sorority house and within twenty-four hours our cultures showed a carrier case in the same house. The case and the carrier were isolated and no further cases developed.

In the twelve years that this system of observation of non-immune contacts has been exercised in lieu of exclusion from college classes, we have been relatively free of secondary and tertiary contact cases in all diseases except chickenpox and mumps. Of the two, mumps is the worse. By observation of the mumps contacts we detect the parotitis early but apparently not early enough to prevent its spread to others. Of five non-immune mumps contacts in one fraternity house, four eventually acquired the disease at intervals

of 15 to 22 days. If mumps should ever become epidemic at Cornell University, I feel that we would be justified in excluding our non-immune contacts from classes, rather than observing them according to our present system.

As soon as a communicable disease case has been removed from a house to the Infirmary, I begin disinfection of the contents of the rooms which the case has occupied.

The sheets, pillow cases, pajamas, towels, washcloths and handkerchiefs are boiled in water for fifteen minutes before being sent to a public laundry.

The quilts, blankets, mattress, pillows and bathrobe are brushed and exposed to the outdoor air and sunlight for a period of at least eight hours.

The windows are opened and the rooms thoroughly aired for eight hours.

All furniture, woodwork and the floor are thoroughly washed with soap and warm water.

Rugs and upholstered furniture are properly cleansed with a vacuum cleaner or thoroughly brushed and beaten in the open air.

The washbowls are filled with a solution of bichloride of mercury or lysol and allowed to remain so for two hours before draining the disinfectant into the sewer.

As to whether this terminal disinfection prevents further cases of illness or not, I cannot say, yet I feel safer in so doing, and I believe it is of educational value to the other students in the house.

Our entire system of control of communicable diseases is of the greatest educational value to the students concerned and its details give the medical advisers ample opportunity to teach the fundamentals of epidemiology. A synopsis of the code printed on large size paper have been distributed to all fraternity and sorority houses and dormitories.

I believe that the recital of the history of communicable diseases at Cornell University during the past college year will serve as sufficient proof of the efficiency of the system in controlling such diseases by finding early the secondary cases among the contacts observed.

Chickenpox	2 cases	13 contacts	0 secondary cases
Diphtheria	1 case	12 contacts	0 secondary cases
Encephalitis			
Lethargica	4 cases	58 contacts	0 secondary cases
German Measles	9 cases	92 contacts	2 secondary cases
Mumps	42 cases	397 contacts	12 secondary cases
Scarlet Fever	7 cases	152 contacts	0 secondary cases
Whooping Cough	1 case	0 contacts	0 secondary cases
Total Communicable Diseases exclusive of catarrhal diseases of respiratory tract	66 cases	724 contacts	14 secondary cases

THE CONTROL OF COMMON COMMUNICABLE DISEASES AT CORNELL UNIVERSITY *

By A. G. GOULD, M.D.,

Assistant Professor of Hygiene and Assistant Medical Adviser, Cornell University, Ithaca, N. Y.

FOR at least ten years there has not been an excessive amount of communicable diseases at Cornell University, if we exclude the catarrhal diseases of the respiratory tract. Their comparative absence, however, should not and has not decreased our efforts to work out suitable steps towards their control. One can readily see that in a student body of five thousand and a faculty community of several thousand more people, in close contact in class-rooms and in their social and fraternity lives, how easily an epidemic of disease might arise. In such a case the source of the infection might not be in the university community itself but among the inhabitants of the "lay" part of the town or even in some community hundreds of miles distant visited by one of our athletic teams and its student followers, or by a student on leave of absence for social or business purposes. I have noted for several years that most of our so-called "children's disease" cases arise from infection acquired during a vacation either at Thanksgiving, Christmas or Easter time. For several weeks following such vacations, cases of illness arising in the student body are carefully scrutinized for signs of contagious diseases.

I am taking it for granted that you know our campus drinking water comes from a watershed patrolled and inspected by a University officer and that daily water analyses are made of water which has passed through the University filtration and chlorination plant.

The University food-handlers receive a physical examination at least once a year and their feces are examined by the state department of health for the bacilli of typhoid and paratyphoid fevers and dysentery.

All of the milk sold in the city of Ithaca comes from tuberculin tested herds and much of it is pasteurized in addition.

We have recently put into action a regulation that all students matriculating in the University must present a satisfactory certificate of vaccination against smallpox, this certificate to be considered satisfactory only if it certifies to a successful vaccination within five years or certifies that at least three unsuccessful attempts have been made within the same period. Last year we ran a successful vaccination campaign for students already matriculated and who had not been successfully vaccinated within a five year period. Many vaccinoïd reactions resulted while others showed immune reactions.

Students may receive typhoid vaccine if they wish.

When a case of communicable disease occurs in the student body or faculty, a list of contacts is secured from the ill individual. If he lives in a fraternity house, it includes all of the members eating or sleeping there and the waiters. If he lives in a rooming house or dormitory the list includes all of those who have been in contact with him during the period of illness. To this list are added the names of other contacts in class-rooms, on athletic teams if the sick person is an athlete, partners at dances, etc. In preparing this list of contacts I realize that frequently I make it too comprehensive, yet I prefer to err in that manner, rather than to make my contact list too meager. This list of names obviously contains some who are immune to the disease in question. The next logical step is then to separate the immune and non-immune contacts. I am aided in the separation by individual history cards which each student makes out during his Freshman year and leaves on file in our office. On these cards, each student checks the names of the diseases which he has had.

Errors naturally occur but as a whole the checking is very satisfactorily done. By referring to these cards I am able to decrease my list of names to those who are non-immune contacts.

The New York State Department of Health has published and enforces certain rules for the isolation and exclusion from school of children suffering from communicable diseases and of children who are non-immune contacts.

About twelve or thirteen years ago the question arose as to whether Cornell University was a school and its students school-children. If so, they must be governed by these state department of health rules in regard to communicable diseases. That would mean that the non-immune contacts of a case of measles would have to remain away from college classes for 14 days. If the disease was chickenpox, they would have to isolate themselves 20 days and so on for the various communicable illnesses.

This mode of procedure seemed rather stiff for college students. Probably some of our so-called non-immune contacts were immune and whether immune or not, to miss two or three weeks of college classwork would invariably result in a poor term of scholastic work if not complete failure.

With the approval of the New York State Department of Health, and others, a sanitary code for Cornell University was devised and adopted.

* Read at the sixth annual meeting of the American Student Health Association, New York City, December 29, 1925.

in January, 1925, to be followed in regard to the control of communicable diseases among its students and teaching staff, and one of the University physicians was commissioned as a deputy city health officer to enforce this code, the details of which had been unofficially followed since 1912

This code substitutes for isolation of non-immune student contacts, a period of observation by the University medical advisers. The non-immune contacts are permitted to attend their classes and other gatherings providing they carry out the terms of the observation period. Failure to obey these terms results in the student being isolated in the University Infirmary for the remainder of the observation period. This code applies also to the teaching staff. Co-operation in general is excellent. Last year one of our instructors served a sentence in the Infirmary for failure to comply with the code and the efforts of the full professors in his department failed to secure his release or even mitigation of his sentence. Because of these "teeth" in the code it is readily administered.

The code also specifies the length of quarantine of the communicable diseases, conditions necessary for discharge from quarantine, who shall visit the ill persons, etc.

Under this type of regulation, our non-immune contacts of chickenpox must report to a medical adviser every other day throughout a period of 22 days from the last day of contact. German measles—every 2 days throughout a period of 21 days from last day of contact. Scarlet fever—every day throughout a period of seven days from last day of contact, and so on for the entire group of communicable diseases. The contact is instructed in regard to the early signs and symptoms of the disease to which he has been exposed and told to report to the medical adviser at once should he note any of these signs or symptoms on a day on which he was not required to report.

The noses and throats of our diphtheria contacts are immediately cultured. Last year a case of diphtheria occurred in a sorority house and within twenty-four hours our cultures showed a carrier case in the same house. The case and the carrier were isolated and no further cases developed.

In the twelve years that this system of observation of non-immune contacts has been exercised in lieu of exclusion from college classes, we have been relatively free of secondary and tertiary contact cases in all diseases except chickenpox and mumps. Of the two, mumps is the worse. By observation of the mumps contacts we detect the parotitis early but apparently not early enough to prevent its spread to others. Of five non-immune mumps contacts in one fraternity house, four eventually acquired the disease at intervals

of 15 to 22 days. If mumps should ever become epidemic at Cornell University, I feel that we would be justified in excluding our non-immune contacts from classes, rather than observing them according to our present system.

As soon as a communicable disease case has been removed from a house to the Infirmary, I begin disinfection of the contents of the rooms which the case has occupied.

The sheets, pillow cases, pajamas, towels, washcloths and handkerchiefs are boiled in water for fifteen minutes before being sent to a public laundry.

The quilts, blankets, mattress, pillows and bathrobe are brushed and exposed to the outdoor air and sunlight for a period of at least eight hours.

The windows are opened and the rooms thoroughly aired for eight hours.

All furniture, woodwork and the floor are thoroughly washed with soap and warm water.

Rugs and upholstered furniture are properly cleansed with a vacuum cleaner or thoroughly brushed and beaten in the open air.

The washbowls are filled with a solution of bichloride of mercury or lysol and allowed to remain so for two hours before draining the disinfectant into the sewer.

As to whether this terminal disinfection prevents further cases of illness or not, I cannot say, yet I feel safer in so doing, and I believe it is of educational value to the other students in the house.

Our entire system of control of communicable diseases is of the greatest educational value to the students concerned and its details give the medical advisers ample opportunity to teach the fundamentals of epidemiology. A synopsis of the code printed on large size paper have been distributed to all fraternity and sorority houses and dormitories.

I believe that the recital of the history of communicable diseases at Cornell University during the past college year will serve as sufficient proof of the efficiency of the system in controlling such diseases by finding early the secondary cases among the contacts observed.

Chickenpox	2 cases	13 contacts	0 secondary cases
Diphtheria	1 case	12 contacts	0 secondary cases
Encephalitis			
Lethargica	4 cases	58 contacts	0 secondary cases
German Measles	9 cases	92 contacts	2 secondary cases
Mumps	42 cases	397 contacts	12 secondary cases
Scarlet Fever	7 cases	152 contacts	0 secondary cases
Whooping Cough	1 case	0 contacts	0 secondary cases

Total Communicable Diseases exclusive of catarrhal diseases of respiratory tract
66 cases 724 contacts 14 secondary cases

THE CONTROL OF COMMON COMMUNICABLE DISEASES AT CORNELL UNIVERSITY*

By A. G. GOULD, M.D.,

Assistant Professor of Hygiene and Assistant Medical Adviser, Cornell University, Ithaca, N. Y.

FOR at least ten years there has not been an excessive amount of communicable diseases at Cornell University, if we exclude the catarrhal diseases of the respiratory tract. Their comparative absence, however, should not and has not decreased our efforts to work out suitable steps towards their control. One can readily see that in a student body of five thousand and a faculty community of several thousand more people, in close contact in class-rooms and in their social and fraternity lives, how easily an epidemic of disease might arise. In such a case the source of the infection might not be in the university community itself but among the inhabitants of the "lay" part of the town or even in some community hundreds of miles distant visited by one of our athletic teams and its student followers, or by a student on leave of absence for social or business purposes. I have noted for several years that most of our so-called "children's disease" cases arise from infection acquired during a vacation either at Thanksgiving, Christmas or Easter time. For several weeks following such vacations, cases of illness arising in the student body are carefully scrutinized for signs of contagious diseases.

I am taking it for granted that you know our campus drinking water comes from a watershed patrolled and inspected by a University officer and that daily water analyses are made of water which has passed through the University filtration and chlorination plant.

The University food-handlers receive a physical examination at least once a year and their feces are examined by the state department of health for the bacilli of typhoid and paratyphoid fevers and dysentery.

All of the milk sold in the city of Ithaca comes from tuberculin tested herds and much of it is pasteurized in addition.

We have recently put into action a regulation that all students matriculating in the University must present a satisfactory certificate of vaccination against smallpox, this certificate to be considered satisfactory only if it certifies to a successful vaccination within five years or certifies that at least three unsuccessful attempts have been made within the same period. Last year we ran a successful vaccination campaign for students already matriculated and who had not been successfully vaccinated within a five year period. Many vaccinoid reactions resulted while others showed immune reactions.

Students may receive typhoid vaccine if they wish.

When a case of communicable disease occurs in the student body or faculty, a list of contacts is secured from the ill individual. If he lives in a fraternity house, it includes all of the members eating or sleeping there and the waiters. If he lives in a rooming house or dormitory the list includes all of those who have been in contact with him during the period of illness. To this list are added the names of other contacts in class-rooms, on athletic teams if the sick person is an athlete, partners at dances, etc. In preparing this list of contacts I realize that frequently I make it too comprehensive, yet I prefer to err in that manner, rather than to make my contact list too meager. This list of names obviously contains some who are immune to the disease in question. The next logical step is then to separate the immune and non-immune contacts. I am aided in the separation by individual history cards which each student makes out during his Freshman year and leaves on file in our office. On these cards, each student checks the names of the diseases which he has had.

Errors naturally occur but as a whole the checking is very satisfactorily done. By referring to these cards I am able to decrease my list of names to those who are non-immune contacts.

The New York State Department of Health has published and enforces certain rules for the isolation and exclusion from school of children suffering from communicable diseases and of children who are non-immune contacts.

About twelve or thirteen years ago the question arose as to whether Cornell University was a school and its students school-children. If so, they must be governed by these state department of health rules in regard to communicable diseases. That would mean that the non-immune contacts of a case of measles would have to remain away from college classes for 14 days. If the disease was chickenpox, they would have to isolate themselves 20 days and so on for the various communicable illnesses.

This mode of procedure seemed rather stiff for college students. Probably some of our so-called non-immune contacts were immune and whether immune or not, to miss two or three weeks of college classwork would invariably result in a poor term of scholastic work or in complete failure.

With the approval of the New York State Department of Health, and others, a sanitary code for Cornell University was devised and adopted.

* Read at the sixth annual meeting of the American Student Health Association, New York City, December 29, 1925.

frequently spring from the numerous small masses of aberrant salivary gland tissue constantly found in the lips, lying between the mucous membrane and the orbicularis muscle. They are of varying density owing to mixed proportions of glandular, fibrous, cartilaginous and myxomatous tissue. They grow slowly, are encapsulated, but may cause deformity, or undergo malignant degeneration, forming the rarer type of malignant tumor of the lip.

Epithelioma sometimes develops from the bite of an animal or an insect. It is a constant claim that it develops from a point of irritation, a jagged tooth injuring the skin, the irritation of a pipe on the lips, the heat from smoking, the irritation of nicotine, etc. In fact, it is reasoned that the tongue and mouth are common sites of malignancy because of the wide possibilities of irritation. Prolonged chewing of any irritating substance may cause a condition bordering on malignancy. In India, cancer of the tongue and mouth is of relatively frequent occurrence in consequence of the chronic aggravation produced by the chewing of the betel nut. Perhaps the most frequent cause of irritation arises from smoking, since the mechanical aggravation caused by the pipe or cigar often produces the incipient lesion which eventually becomes malignant. Scar tissue is more susceptible to degeneration than normal tissue, in the mouth as elsewhere. Decayed and jagged teeth, ill-fitting crown and bridge work, poorly made dental plates or repeated traumatism may create irritation from which a precancerous condition and, later, a malignant process may arise.

Jacobson includes many forms of irritation as precancerous conditions, chronic glossitis, with hypertrophy and fissuring, chronic atrophic glossitis, papillomas and ulcers, leucoplakia and ichthyosis.

Leucoplakia buccalis first appears as a bluish white or bluish red (more rarely) patch or patches on the mucosa, which are sensitive to chemical or thermal irritation. Later a pearly or milky white patch, slightly indurated, is seen on the mucous membrane of the tongue, cheeks or gums. Cracking or fissuring with ulceration are late stages, the first two frequently the result of syphilis, while any extensive ulceration usually means cancer. Microscopically the lesion shows an inflammatory process in the papillary region with secondary hyperkeratosis. The lesion is extremely rebellious to treatment and is distinctly precancerous, 30 per cent have been found to be malignant, all are potentially so.

Cancer of the lip is confined almost entirely to men, while the women who suffer from it, are, as a rule, smokers. Over 95 per cent are on the lower lip. All ages are affected, the cases on record embrace the years between 24 and 93, the average age is 54. A large group of cases were preceded by persistent chapped lips, kera-

toxis, seborrhoea or leucoplakia. This group shows a great tendency to re-occurrence of the disease after treatment.

Basal-celled epithelioma most frequently occurs in elderly people who have led an out-of-door life, such as cab-drivers, sailors, and farmers. The lesion occurs on the parts most exposed to the elements of wind, sun, cold, etc., and for this reason the face and hands are chiefly affected. X-Ray burns, from treatment over a period of time, may simulate the same weather-beaten appearance, and may lead also to the development of a rodent ulcer.

The diagnosis of epithelioma must, in many instances, be made microscopically. Gumma, leucoplakia, epithelial hyperplasia, broken-down tuberculoma not associated with pulmonary tuberculosis may all simulate carcinoma. Lupus is frequently hard to distinguish from epitheliomata, and not only that, but epithelioma commonly develops on an old lupus ulcer. Actinomycosis and blastomycosis must be excluded. Simmons has found it a safe rule that any ulcer is carcinoma until proven otherwise.

Few early cases, unfortunately, are seen by the physician. The early symptoms in a series of 187 cases passing through the Massachusetts General Hospital were as follows: "Sore or cold sore" (83 cases), "scab" (19 cases), "wart or tumor" (38 cases), "pimple, crack, blister, cut or enlarged metastatic glands." The average length of onset of symptoms was one year. The average delay in going to a physician was four to five months. The average delay before operation was one month. Thus the average total time elapsing since the onset of the symptoms was one and one-half years. The types of growth of the tumors in this series of cases was: Fungating, 21, ulcerative, 84, tumor, 34, warty, 14, miscellaneous, 19. The patient was generally in much pain and suffering, was weak and emaciated from inability to take food or liquid.

The progress made in the treatment of malignant diseases has been along the following lines: (1) In the ability to apply to the individual case that treatment, or combination of treatment, which experience has shown offers the greatest prospects of benefit or cure, (2) The earlier recognition of the disease from propaganda educating the public, and (3) Treatment of early malignant conditions.

The general factors on which the indications for treatment depend are:

- (1) Location, character, progress, extension and metastases of the tumor
- (2) Patient's general condition
- (3) Histopathology of the tumor
- (4) Training and experience necessary to make proper choice of method offering greatest possibility of cure

A realization of the fact that the patient should be given every possible chance throws

EPITHELIOMA OF THE FACE AND BUCCAL CAVITY *

By J O WETZEL, BS, MD, OSSINING, N Y

OF all epitheliomata, 70 per cent occur on the face, 6 per cent on the hand, and the balance on various other parts of the body. Of the 70 per cent on the face 20 per cent occur on the lips, 13 per cent on the eyelids, 16 per cent on the nose, and the balance on the ear, cheek, forehead, with a small percentage on the tongue and buccal walls.

Epitheliomata, or as Ewing suggests, Epidermoid Carcinomata would be a better name, are histologically of two distinct types, viz

- 1 Basal-celled epitheliomata
- 2 Squamous-celled epitheliomata

The basal-celled epitheliomata develop from the malpighian layer of the skin and are of two types, viz

- 1 The reticulated epitheliomata
- 2 The adenoid epithelioma

The reticulated form becomes the rodent ulcer. The rodent ulcer develops anywhere on the face, nose, neck or ear. It begins as a small flat papule or smooth wart and remains in that condition a long time, but breaks down into an ulcer which slowly enlarges until it may eat off a large part of the nose, ear or face. The ulcer is as a rule shallow, but there comes a time when it eats deeply until it reaches the bone or deep fascia, where it is checked for a long time, but eventually it destroys these deeper structures. This is the so-called crater-form ulcer. Like all basal-celled epitheliomata, it does not metastasize, and in that sense is not malignant. But it finally destroys the patient though it is many years in doing it.

Any basal-celled tumor, including the rodent ulcer, may at any time have a squamous-celled epithelioma engrafted on it, especially at some portion of the margin, and the rodent ulcer has a habit of healing at one point while it advances at another.

The adenoid epithelioma is a basal-celled tumor which resembles an adenoma, but it is composed of basal cells with generally a mixture of squamous cells, and not of secreting cells like the true adenomata. It, like the rodent ulcer, begins as a papule which breaks down into an ulcer which has little tendency to heal, although in the early stages frequently skins over and remains healed for a time, only to break down again. Often the ulcer edge is thickened and indurated, the center secreting a glairy liquid that crusts and becomes a black scab, which usually has a clean base under it when it is removed, but very often there is a drop of pus under it. Again the ulcer is raised above the surrounding skin, is soft and spongy, and is red or brownish in color. The adenoid epithelioma, like the rodent ulcer, does not metastasize early

and usually not at all. Its clinical course is more rapid, and it kills the patient in a much shorter time, but even then it takes several years to accomplish this end.

The squamous-celled epithelioma differs from the basal-celled epithelioma in that it is far more malignant, metastasizes early into the lymph channels and glands, and destroys the patient in much less time, though it generally requires several years to accomplish it. However, a few are rapidly fatal. They are generally single, but sometimes multiple and may be found almost anywhere on the skin. In their early stages they may be marked by erythema, seborrhoea, eczema or pruritis (Ewing). They are also of two types.

The first type appears as a warty growth in which condition it may remain for a long time, but slowly grows larger at its edges. In this stage it is quite amenable to treatment but later it spreads in size, ulcerates, and metastasizes into the neighboring lymphatics. Then treatment is a serious problem.

The other type does not begin as a wart but as a depression which early becomes fixed to the underlying tissues and ulcerates early into the lymphatics, loses its squamous-celled appearance, and takes on the aspects of a tubular carcinoma. This type is malignant, fatal, and destroys life much earlier than any other form of epithelioma.

All forms of epitheliomata, when they metastasize, do so into the nearby lymph vessels and glands, and only rarely does metastasis appear in distant organs. This is especially true of those of the face, mouth and tongue, which metastasize into the cervical and submaxillary glands. These tumors ulcerate early, become infected with pus organisms, especially streptococci, so that local or general sepsis complicates the general course. Squamous-celled epitheliomata (acanthomata) are prone to develop where the skin joins the mucous membrane, as on the lips, and it is a clinical point worth noting that if an epithelioma begins on the skin surface of the lip it is far less malignant than if it develops from the mucous surface, and it is apt to be very malignant if it develops from the inner side of the lip margin.

Cancers involving the mucous membranes of the buccal cavity may be roughly grouped into lesions involving the lower lip and the corner of the mouth, the tongue, primary lesions of the floor of the mouth, the tonsil, and in the mucous membrane covering the cheeks, the alveolar processes, the palate and the pillars. The disease in each of these anatomical structures requires separate consideration.

The so-called salivary gland tumors not in-

ably little shock and almost no pain following the operation, even in cases where large areas have been burned, as for instance, carcinoma of the breast. It seems wise to give carefully planned X-ray treatment preliminary to the removal of the malignant growth with the cautery.

Surgical diathermy by the needle method seems to have the following advantages: tumors otherwise inoperable may be attacked, the operation is more or less bloodless, the danger of metastasis is much less than with a cutting instrument, owing to the sealing of the blood vessels and lymphatic draining the parts, sterilization of the parts, there is a complete destruction of the viable and palpable malignant disease, the operation is rapid and easy, there is no surgical shock, convalescence is rapid, formation of adhesions is rare, the operation can be repeated if necessary. The disadvantages of this method are: healthy and diseased tissue are equally destroyed, the surgeon cannot see important vessels and nerves, there is danger of secondary hemorrhage when operating near large blood vessels, there is a tendency to the formation of keloid in operations involving skin surfaces.

Of the other methods of treatment it may be briefly stated that pastes and caustics are painful, inefficient and deceptive, fulgeration, coagulation necrosis with dull heat, and X-ray are not sufficient to use alone, and that a lethal dose must be given with radium or X-ray if these forces are to be used at all. Implantation of radium gives better results than surface irradiation.

The auricle is a vestigial organ, of little use, and a frequent cause of trouble, possibly because it is vestigial, and also because it stands out on the side of the head exposed to the elements. It is frequently affected by keratotic patches, and by epitheliomata either developing on these patches or arising from the more deeply situated cutaneous glands and hair follicles. Most cancers of the auricle are of the basal-celled type, and not very refractory, except when they become extensive and invade the comparatively less attainable external auditory meatus. Epithelioma of the ear, as in other situations, assumes a great variety of appearances, such as a small dry ulcer with rolled borders, a crust with a degenerated base, a cutaneous horn or an advancing cicatrizing growth. Successful irradiation would be impossible if it were not for the fact that the ear is a flap-like organ, capable of being attacked on both sides, this subjecting the growth to cross fire. This is the treatment of choice for successful cosmetic effects as well.

All the basal-celled epitheliomata are easy

to cure in the early stages. Removal with knife, actual cautery, or caustics, will cure them if done thoroughly, and even pastes will cure the most of them. Diathermy will cure them and X-ray or radium will remove them readily, and generally without any scar. The basal-celled epithelioma is the reason for the numerous quack cancer cures and furnishes the livelihood of cancer quacks, because this individual with his paste or caustic or whatever he uses does cure most of the basal-celled epitheliomata that he treats. The pain of the paste or caustic may be severe, but the patient gets rid of the tumor without being "cut" and he is satisfied. Naturally, he does not know the difference between his basal-celled epithelioma and a real cancer, neither does the charlatan for that matter, so he sends all the cancer sufferers to the charlatan that he comes in contact with, using his own case as a glowing example of cure. So where one non-malignant epitheliomata or keratosis is cured, many real cancers are tampered with and made worse, the patient's sufferings enhanced by the treatment.

The formulated procedure for radical excision of a malignancy about the jaw and mouth is the removal of the entire maxilla or mandible, in the case of the lower jaw, from the mid-line or beyond in front, to the articulation or near it in the back, together with all the soft tissues possibly invaded, in the case of the superior maxilla, the entire bone from malar to nasal attachment, orbital plate, palatal process, and soft parts possibly invaded. To this is added a block dissection of the lymphatics of the affected area. This surgical treatment might be profitably combined with coagulation necrosis at a dull heat and the use of radium. Butler (1909) found that with delay of ten days to three weeks in the removal of the lymphatics, his mortality rate was reduced from 31 per cent to 23 per cent, complications were diminished (shock, infections, metastases), and the longevity of his patients was increased.

In the treatment of cancer of the tongue, Bainbridge advises that all precancerous lesions should be removed, abnormal manifestations of irritation should be eradicated, in advanced cases, operation as radical as is compatible with life should be performed, when it is impossible to fully remove the growth, a palliative operation, with ligation of the lingual and external carotid arteries or cutting of the dental nerves, may lengthen life and alleviate suffering, in inoperable cases yeast may be held in the mouth to reduce the fetid condition, while radium, caustic or cautery may be used as palliative measures.

The surgical indications for squamous-celled epithelioma of the lip vary with Broeder's

the entire responsibility of education, prevention, early diagnosis and treatment upon the physician. What Judd has to say about carcinoma of the tongue applies with equal force to associated lesions.

(1) A reduction in the number of cases of carcinoma of the tongue depends upon the early recognition and proper treatment of precancerous lesions.

(2) Lesions of the tongue, suspected of being malignant, should be excised for diagnosis, and should not be treated locally.

(3) Improvement in the end results of treatment of carcinoma of the tongue depends on early diagnosis and proper early treatment.

(4) All the patients with operable carcinoma of the tongue should be given the benefit of surgery, including the cauterization of the local lesion and excision of the glands of the neck. Radium should also be employed in order to give these patients every possible chance.

In making the diagnosis it is not sufficient to say benign or malignant, the degree of malignancy must be definitely stated, using as an index of malignancy the cellular activity of the embryonic forms in the tumor. Broeders furnished a very useful classification of relative malignancy when he divided the epitheliomata of the lip into four classes.

(1) Three-fourths differentiated cells and one-fourth undifferentiated. No mitotic or "one-eyed" cells.

(2) Essentially equal quantities of differentiated and non-differentiated cells. Occasional mitotic figures and "one-eyed" cells.

(3) One-fourth differentiated cells and three-fourths undifferentiated. Numerous mitotic figures and "one-eyed" cells.

(4) All undifferentiated cells with numerous mitotic figures and "one-eyed" cells.

This classification furnishes the basis for choice of treatment, especially by those who do not use surgical methods. For instance, the radiologists have found that group one is resistant to radium, while it yields readily to surgical treatment. Conversely, they claim that group two, which offers a poor surgical prognosis, and groups three and four, which are most susceptible to irradiation, should always receive radiotherapy, either alone, or in combination with surgery. Their other arguments are that as previously radiated carcinoma cells do not metastasize well, there must always be an adequate preliminary radiation, also, facilities for the use of radium emanations permit of a more elaborate technique with a higher percentage of cures and a better cosmetic effect. Against this the surgeon will argue that surgery fails only when the disease cannot be reached or eradicated, when there are metastases radium is not effective and surgery seldom so. Clinical cures, so called, are not backed up by follow-up records from the radium

clinics. A group four carcinoma should have surgery because we cannot afford to give precedence to any physical agent where proper surgery holds out proven opportunities for a cure. Early cancer, extensive operation, late cancer, little or no surgery.

In an effort to conciliate the above seemingly opposite views, Pancoast offers the following. The radiologist is endeavoring by every possible manner of investigation to contrive means of accomplishing what surgery has failed to do. He receives and treats the worst wrecks wrought by cancer. Surgical methods would be ideal, if some means of education could inculcate in the mind of every individual that every ulcer, fissure or keratosis of the lip persisting for several weeks, especially if showing induration, and if syphilis be excluded, is either cancerous or potentially so, and that such an area should be removed. The vast majority of lip cancers have, unfortunately, gone beyond this stage when first seen. The general run of cases as we see them may be divided into three groups, from the standpoint of methods of treatment, prognosis and statistics, as follows: preliminary lesions without any evidence of metastasis, cases presenting small, palpable nodes in the submental or submaxillary triangles, and those with advance primary lesion and large nodes in these areas or in other gland groups. Frequency of local recurrence following surgery shows that the results should be better, and surgery alone cannot be regarded as a complete method of treatment in view of our present knowledge of the results of radiation.

Cases of epithelioma that are not entirely cured by the first treatment of radium or X-ray may be greatly stimulated in their growth by a subsequent treatment. Best results in these cases follow a wide excision of the tumor, otherwise the patient succumbs. Also, the prognosis is vastly more favorable with actual cautery than with the knife. The cautery should be applied in many cases that are apparently hopelessly advanced, because this group contains a considerable number which will remain permanently well after removal with the actual cautery. The effect of the tremendous heat radiating from the cautery iron seems to extend a considerable distance beyond the tissues that are actually destroyed. The ordinary small-size soldering iron makes an exceedingly satisfactory instrument for use in this operation. It seems best to keep the cautery in contact continuously at each point for a sufficient time to get the effect of the heat at a considerable depth, rather than by simply passing the cautery back and forth quickly, which will simply destroy the tissues with which it comes in contact. The method can be applied with equal advantage to sarcoma and carcinoma. There is remark-

semination and more rapid growth. In operations for cancer of the buccal mucous membrane, a "platter" of underlying bone should be removed, together with the intact growth. No cancer tissue should be cut or handled.

In support of the soundness of the above principles, Crile cites 224 cases of carcinoma of the buccal surfaces, especially mouth, tongue and jaws, with 6 operative deaths.

In determining the relationship of cellular differentiation, fibrosis, hyalinization and lymphocytic infiltration of the tumor to post operative longevity of patients with squamous-celled epithelioma of the lip, it was found in a series of cases at the Mayo Clinic that each of the above factors should be considered as a defense, and that the presence of anyone or a combination of these factors tends to increase post-operative life.

The mortality rate of cancer of the lip, arranged according to Broeder's classification is as follows:

Group	Mortality	Percent with Disease
1	11.21	15.82
2	33.33	61.10
3	75.38	21.40
4	100	11

These figures check very closely with those obtained from other clinics.

In comparing the prognosis following radical or local operation, the following figures of Simmons are illuminating: operative mortality, 2½% on radicals, local operation only 66% well radical with no lymphadenopathy, 92% five year cures, radical with adenopathy, 34% five year cures.

Loos, Steiner and Janowsky proved that a five year period should be the standard in judging a cure from malignancy.

classification. A conservative operation is advised for group one, depending upon size and location, while remembering that it is impossible to differentiate between an inflammatory enlargement of lymph glands and glandular metastasis by palpatory examination. The incision should not be a V-shaped in a vertical direction, because the trend of growth in cancer of the lower lip is outward and downward, and the usual metastasis is to the submaxillary rather than the submental group of glands. The tendency is to spread to the inner side rather than to the skin side. In epithelioma of groups two and three, when no glandular metastasis is present, complete removal of the cancerous area, together with a complete removal of all gland-bearing tissue from the submaxillary and submental triangles of the neck on both sides, when glandular metastasis is present, the cervical glands not being involved, and only one group of the submaxillary and submental glands involved, complete removal of the cancerous area, together with the removal of the upper superficial and deep cervical glands of that side of the neck corresponding to the metastatic growth. When two or more groups of glands or when the cervical glands are involved, complete removal of the carcinomatous area, together with a complete block dissection of that side of the neck corresponding to the involved area, sacrificing the sternomastoid, omohyoid muscles, and the spinal accessory nerve, and a dissection of the submental and submaxillary triangles of the opposite side. Although such radical surgery will often prolong life, a five-year cure is not to be expected in these cases. In epithelioma coming under group four, the killing power of the tumor is 100 per cent, and it is useless to subject these unfortunate patients to a major operation. Palliative treatment only is indicated.

Among 4,500 reported autopsies of cancer of the head and neck, in only 1 per cent were secondary foci found in distant organs or tissues. Death results from local and regional development of the disease, and not by distant invasion. The collar of lymphatics about the neck forms an almost impossible barrier through which cancer rarely penetrates, and every portion of the barrier is readily accessible to the surgeon.

As far as metastatic dissemination is concerned, therefore, cancer of the head and neck presents a far more favorable outlook than does cancer of the breast, with its thoracic and abdominal metastases, or cancer of the stomach or intestines with its inaccessible retroperitoneal and liver metastases.

Within the lymphatic collar, because of the rich supply of lymph nodes and their connecting channels, metastases are rapidly disseminated,

although cancer of each part of the head seems to follow a law of its own so far as its primary extension is concerned. Thus, cancers of the skin, of the mucous membrane of the cheeks, of the mucous membrane of the edges of the jaw, usually do not metastasize, cancers of the lips almost uniformly metastasize to the lymphatic glands under the jaw, cancers of the floor of the mouth usually metastasize in the glands of the same side. Paired organs or distinctly one-sided foci usually metastasize regularly, while unpaired organs, as the tongue, or mesial tissue, such as the middle of the lip, metastasize irregularly and widely. For example, a marginal cancer of one side of the tongue may metastasize to the glands of the opposite side, although usually low down and towards the clavicle, although the metastasis may occur at any site, high or low, on the right or the left side.

This gives us the first surgical principle—removal en bloc of the pertinent lymphatic glands. Thus, early cancer of the mucous membrane of the gingivae or cheek which metastasizes late does not demand excision of the glands, while cancer of the lip, however early, demands the complete removal of all lymph nodes which drain the involved area, cancer of the tongue or lip calls for complete excision of the glands of the neck on both sides. Cancer of the jaws, which metastasizes rarely, and usually on the side of the lesion demands a less radical operation.

The second surgical principle is suggested by the fact that the most common cause of death after operations which involve the mouth is bronchopneumonia, resulting from the inhalation of blood or of wound secretion. This should always be prevented. Scrupulous hemostasis during operation, tubage and gauze packing of the pharynx, anesthetic per nares with rubber tubes, intralaryngeal catheterization, lightest possible anesthesia in combination with local anesthesia, no ether, specially trained nurses.

The third surgical principle is the prevention of a resowing of the cancer by a wide excision and the control of hemorrhage. Hemostasis may be secured by a preliminary ligation of the lingual, or a dry field may be insured by the employment of a mattress suture in a wide zone around the focus. The primary focus may be destroyed by cautery or removed by excision. Local excision of only the primary focus of the tongue, lip and floor of the mouth, leaving the regional lymphatic glands is as ineffectual as excision of the breast, without removal of the regional glands. Excision of individual lymphatic glands not only does not afford permanent cure, but is usually followed by greater dis-

semination and more rapid growth. In operations for cancer of the buccal mucous membrane, a "platter" of underlying bone should be removed, together with the intact growth. No cancer tissue should be cut or handled.

In support of the soundness of the above principles, Crile cites 224 cases of carcinoma of the buccal surfaces, especially mouth, tongue and jaws, with 6 operative deaths.

In determining the relationship of cellular differentiation, fibrosis, hyalinization and lymphocytic infiltration of the tumor to post-operative longevity of patients with squamous-celled epithelioma of the lip, it was found in a series of cases at the Mayo Clinic that each of the above factors should be considered as a defense, and that the presence of anyone or a combination of these factors tends to increase post-operative life.

The mortality rate of cancer of the lip, arranged according to Broeder's classification is as follows:

Group	Mortality	Percent with Disease
1	11 21	15 82
2	33 33	61 10
3	75 38	21 40
4	100	11

These figures check very closely with those obtained from other clinics.

In comparing the prognosis following radical or local operation, the following figures of Simmons are illuminating: operative mortality, 2½% on radicals, local operation only 66% well radical with no lymphadenopathy, 92% five year cures, radical with adenopathy, 34% five year cures.

Loos, Steiner and Janowsky proved that a five year period should be the standard in judging a cure from malignancy.

STRANGULATED INGUINAL HERNIA IN INFANTS

By FREDERICK S WETHERELL, MD, SYRACUSE, N Y

A REVIEW of the literature on inguinal hernia in infants indicates that opinions differ regarding the proper method of treatment, and that strangulation is not as rare an occurrence as a casual survey of the literature might indicate. It is the purpose of this paper briefly to outline the trend of the literature on this subject, to report a case of strangulated inguinal hernia, and two cases of temporary incarceration, and to arrive at a conclusion regarding the advisability of radical operation in nonstrangulated as well as strangulated hernia.

Although operation has long been generally conceded to be the only means of curing hernia in adults, conservative methods were employed almost exclusively in treating hernia in infants until late in the eighties. At the Surgical Congress of 1888 there was a heated discussion on the relative merits of radical and conservative treatment, the English and French surgeons championed surgery, while the Germans adhered to the old methods. About 1900 the majority of surgeons of all countries had agreed to the necessity of radical operation for children in the first and second years. Although many cases have been reported illustrating the excellent results to be expected following operation, opinion is still divided as to the advisability of radical or conservative therapy, and even those authorities who are strongly in favor of surgery do not agree as to the age most suitable for interference.

From my own experience, and that of writers who have operated on large series of cases of inguinal hernia in infants, it would seem that radical operation is the method of choice and that it may safely be performed at any age. In 1902, the mortality rate for operation following strangulation was 23 per cent, in 1913, it was variously estimated at from 3 to 10 per cent. Since then, the statistics of many surgeons who have operated early on large series of cases, including both strangulated and non-strangulated hernia, reveal an average mortality of 0.5 per cent or less.

In a series of 1,000 operation performed by Herzfeld there was only one death, the infant died on the table before operation was commenced, apparently from status lymphaticus. Other authors who report excellent mortality records are MacLennan, 522 cases with no deaths, Spitzzy, 220 cases, and Ranft, 61 cases with no deaths attributable to operation.

Time, as well as improved aseptic methods, is an important factor in the prognosis. According to Flament, the mortality of untreated strangulation in infants is 37 per cent after the first twenty-four hours, 54 per cent after forty-eight hours, and 78 per cent after seventy-two hours.

Strangulation of inguinal hernia in infants and young children is of comparatively infrequent occurrence. Nussbaum, in twenty-five years' experience with 54,000 children, observed only two cases. In a study of 138,741 cases at nine large German clinics, Stern noted one case of incarcerated hernia in children for every 108 herniotomies in adults. In a consecutive series of 1,500 operations Herzfeld found true strangulation in only three. Fuld reported one case among 1,200 children examined at the Children's Clinic for the Ruptured and Crippled during one year. Porter and Carter believe that strangulated hernias constitute from 5 to 7 per cent of all hernias encountered in the very young. Krause is practically alone in reporting the incidence of strangulation as high as 10 per cent. He believes that in many cases the strangulation disappears spontaneously, and so is not recorded in the surgical statistical reports.

With regard to the average age at which strangulation appears, there is quite general agreement. It seems to be observed most commonly in the first year, but particularly during the first six months. Telford, who collected 112 cases in infants under six months, found that as the age in months increased there was a comparative decrease in the number of cases. That is, in the successive months from one to six the number of strangulation was 34, 27, 24, 12, 6, and 9. One hundred and twenty of 225 cases collected by Estor occurred in infants of six months or less. Knobloch remarks that two-thirds of strangulations occur during the first year.

When a rare condition is encountered in which the diagnosis is so palpably simple as it is in strangulated inguinal hernia in an infant, and yet has been delayed as long as four days, it becomes of great practical importance. Delays of this sort are undoubtedly due to parental ignorance, and parents, particularly in the event of an existing hernia, should be warned of the possibilities of strangulation.

In the majority of cases reported, incessant crying and screaming was the first symptom noticed, followed by vomiting, and often by retention of urine. The need, therefore, of a careful physical examination of an infant presenting these symptoms is very evident. Hydrocele and inflammation of an undescended testicle, or an inflamed gland, must be ruled out, yet, in a confusing case it might be well to cut down on the mass rather than run the risk of gangrene of the intestine.

If the strangulation has been present only a short time, manual reduction by taxis may be tried. The danger of attempting anything but the gentlest taxis must be emphasized, for the

delicate structure of the intestinal wall in an infant is easily ruptured

REPORT OF CASE

December 5, 1920, at 10 00 P M, an infant five months and six days old was seen in consultation with Dr G M Retan, of Syracuse. A diagnosis of strangulated, right inguinal hernia had been made. The infant was well nourished and had been perfectly well until the present attack. The parents had never been aware of the presence of a hernia. The child had been crying incessantly for three hours, and had vomited twice, once at nine o'clock and again at nine-thirty. An attempt at taxis, made very gently, was without result and immediate operation was advised. The baby was removed to the Syracuse Memorial Hospital and operation was performed four and one-half hours after the onset of symptoms.

The tumor, which was about 2 by 3.5 cm in diameter, had slightly increased in size since the diagnosis was first made. The sac was nearly transparent, the contents were a dark bluish red, and irreducible. An incision through the subcutaneous inguinal ring relieved the constriction, and the contents immediately improved in color. They were allowed to slip back into the peritoneal cavity.

The sac was opened, transfixed, and tied high up. Chronic catgut No 1 was used to bring the falx inguinalis over to the shelving border of the inguinal ligament. The cord was not transplanted. The very delicate external oblique aponeurosis was also sutured with chronic catgut No 1 and the skin with silkworm gut.

For a final dressing the usual gauze and adhesive plaster were used as in adults, with the exception that the adhesive was put on in four thicknesses, thus making it practically impervious to moisture. Many dressings have been devised in the attempt to prevent infection of the wound by urine, but it would seem from the result in this case that adhesive in several thicknesses furnishes a simple and efficient dressing. When the dressing was removed on the eighth day, the wound was found dry and clean. The stitches were drawn and there was no sign of wound infection.

The baby continued its nursings beginning the afternoon of the day following operation. Recovery was uneventful, and six months later the child was in excellent health with no sign of a recurrence.

Two cases have been seen within the past four months. One an infant boy of seven months, in which a right inguinal hernia had been incarcerated for four hours. The hernia slipped back soon after the child had been removed to the hospital. At operation, the following day, a sac

1¾ inches in length was found. The same procedure was followed as in the previous case.

The second of these latter cases was an infant girl of eight weeks, in which the mother had noticed a swelling in the right inguinal region the size of a large English walnut two weeks before admission to the hospital. At operation a sac 1½ inches long was found. The method recently described by R. Hamilton Russell, F A C S (Hon.), Melbourne, Australia, was followed in operating this case. It very much simplifies the operation for radical cure in infants and appeals to the author as being based on sound reasoning. The operating time is greatly shortened and not more than 15 minutes need be consumed to complete the entire procedure. Both of these infants made uneventful recoveries. There was no infection of the wound and their stay in the hospital was six days in each case.

CONCLUSIONS

Surgery is the method of choice in the treatment of strangulated or non-strangulated inguinal hernia in infants.

The mortality and prognosis following radical operation are excellent, the average death rate being 0.5 per cent or less.

Taxis does not effect an enduring cure, and is a dangerous procedure.

The only contraindications to operation are the presence of intercurrent disease and a weak, ill-nourished infant.

Some authorities consider operation on the very young infant preferable to operation during the second year, as it interferes less with the general development of the child.

Strangulation in infants and children is observed most commonly during the first year.

TREATMENT OF ACUTE GONOCOCCUS URETHRITIS IN THE MALE

By ALBERT E MAN, M D, NEW YORK

AFTER ten years of experience and study the writer has come to the conclusion that the common practice of injecting fluid into the male urethra for the purpose of achieving disinfection is not only useless but harmful

Gonococcus infection in the male cannot be cured by germicides. In spite of the testimonials of thousands of doctors as to the merits of various silver preparations, chemical dyes, astringents, etc., when used as injections, the writer must emphatically state that "cures" of gonorrhea under such treatment are achieved in spite of, rather than because of such treatment

Without going into dry pathological data let it suffice to say that the gonococcus is inaccessible after three or four days following infection. Further, it is impossible to successfully employ a germicide of sufficient strength to achieve disinfection without damaging the urethral mucosa

It is well known that the gonococcus loses virulence after a more or less prolonged residence in the tissues. It is generally conceded that the individual harboring the gonococcus forms antibodies in his blood serum. It is also well known that rest and nutrition of the proper sort are necessary to increase the resistant powers of the body. The mechanical value of drainage in infection is well understood

In practice, the application of these well known facts will not only cure primary acute gonorrhea but will prevent complications. Gonorrheal epididymitis, prostatitis, vesiculitis, rheumatism, heart disease, are accidents usually directly traceable to the injection method of treatment

Rest must be absolute. The patient must be

put to bed. Nutrition must be maintained at a high level. Alkaline fluids in great quantities should be administered. A good, potent, freshly prepared vaccine should be administered from the beginning of the treatment. If the meatus is small and hinders drainage, perform a meatotomy. The bowels must be kept open. Sandalwood oil may be administered internally for its soothing effect. After the irritation and discharge have somewhat subsided, discontinue sandalwood and alkalies and give hexamethylene and acid sodium phosphate in large doses four times daily. Discontinue if urine becomes cloudy or bloody. Hexamethylene is impotent in any but acid urine. It is used for its prophylactic value. After the discharge has subsided, warm irrigations of 1/14000 to 1/10000 of silver nitrate may be given. This is not used for its germicidal effect but for its value as a stimulant to the urethral mucosa

When the urine is fairly clear and the discharge is negative, examine the anterior urethra with an electrically lighted urethroscope for infections of Littre's glands. They must be destroyed by the cautery if found to be infected. Results of previous attacks, such as strictures, prostatic and vesicular infections are to be searched for and treated along the usual lines accepted as effective for these conditions

In the chronic posterior cases, sounds and irrigations of 1/12000 silver nitrate prostatic and seminal vesicle massage are of accepted value

No case should be discharged as cured without exhaustive laboratory tests such as are now recognized and commonly practiced

The usual injunctions as to alcohol, spiced foods, sexual excitement and eye hygiene should not be overlooked

VACATION

The time for the long vacation is at hand, but the dates set for the fortnightly issues of the JOURNAL will continue to make their relentless appearance, and the printer's hunger for copy will be insatiable. However, editors are receiving letters asking that articles be deferred until the fall season when the readers of the JOURNAL will be in a more receptive mood.

Doctors will go to the mountains and the seashore with supplies of reading and writing material, but the magazines will remain uncut and the fountain pens will not need refilling. The JOURNAL will adopt a modest course during the

summer months and the articles, in keeping with the doctors' moods, will be contemplative rather than argumentative.

The Summer issues of this Journal will not be devoted to special topics as several of the recent numbers have been. This decision is based largely on the appeals of prospective contributors that intensive requirements of preparation be deferred until the reassembling of their office personnels in the Fall.

Accounts of medical society picnics and other social activities are especially solicited.

DEMOCRACY OF PHYSICIANS

The Medical Profession is composed of all sorts of physicians whose temperaments and talents are as diverse as those of farmers, or lawyers, or engineers. A county medical society is composed of those same doctors—the brilliant and the mediocre, the original thinkers and the imitators, the resourceful and the bookworms, the public spirited and the self-centered, the ambitious and the complacent, the active and the sluggish, the adaptable and the misfit, and so on through the list of characteristics.

Every doctor exhibits an incongruous mixture of characteristics. It almost seems that when an individual was born, one characteristic from each pair of traits was assigned to him by lot—a good one and a bad one, or possibly a succession of good ones and then a bad one which is utterly inconsistent with the rest of his characteristics.

Psychologists say that about twenty well-defined characteristics and temperaments are inheritable, and that combinations of these make up one's individuality which distinguishes him from all other persons.

The medical profession, like a manufacturing concern, is made up of two great classes—the producers and the salesmen. On the one hand are those who are dominated by a scientific instinct and are found in laboratories and research organizations, on the other hand are the physicians who sell medical service as they come in contact with the public.

The salesmen among physicians may be divided into the salaried doctors and those in private practice. Some physicians prefer to be relieved of financial responsibility. Those accept positions in departments of health, insurance companies, and lay organizations, or if they do private practice, they are known as good doctors but poor business men. Other physicians delight in business contacts and in the art of the routine practice of medicine, preferring to send their specimens to a laboratory and to call in scientific

specialists for the diagnosis and treatment of their difficult cases.

There is an element of friction and antagonism between the producing doctors and the salesmen. The salaried public health worker may call the private practitioner commercial, and the family doctor may say that the health officer is impractical. The great medical problem of the present day is to harmonize these two groups of medical men—and the Medical Society of the State of New York is doing it.

While physicians exhibit diverse traits and aspirations, yet those which are the common possession of all doctors are in overwhelming proportion—seventy-five per cent or more. Doctors may differ in twenty-five per cent of their characteristics, but there is no need that they be antagonistic in any.

The great work of the medical societies of the counties and the state has been the unification of the medical profession. The members of the societies give the leaders in each branch of medicine the permission to speak for their less informed brethren and to act as the spokesmen for those who have neither the inclination nor the talent to speak and write and act in a public capacity.

Every County Medical Society is a democracy in which there is an equality of opportunity, and a freedom for each member to act according to his talents. The great majority of its members will do little else than treat sick individuals. There will probably be one doctor who will address meetings, another who will write articles for the local papers, another who will provide entertainments for the meetings of the Society, and another who will represent the Society at conventions away from home. The Society provides an opportunity for every member to use the talent which he possesses. Diversity of characteristics no longer keeps the doctors apart—it is the basis of the strength of medical societies, in that every gift of every person may be put to use.

THE AVAILABILITY OF MEDICAL SERVICE

Every now and again some layman brings up the great need of a doctor in his community. The question crops up in the whole nation as well as New York State. It has been thoroughly investigated in New York, and the evidence is that medical services are more readily available now than ever before in practically every part of New York State. Physicians as well as stores, churches, movie theatres, and schools tend to centralize themselves in cities and county seats. The telephone and the automobile bring urban

advantages within reach of nearly all rural dwellers.

The State Department of Health and later the State Medical Society have investigated every request for medical personnel, and rarely has a need been found to induce a doctor to settle in any community that is without a doctor.

Theoretically there should be a scarcity of doctors. Almost half of the former medical schools have closed, and those that remain have reduced the number of their students. Yet New

York State seems to maintain its standard of about one doctor to every 750 people

Since there is a concentration of doctors in the cities, it would be supposed that Greater New York would have an oversupply, but the great Borough of Brooklyn—the most populous one—has about the same average as the rest of the State. Queens Borough has one doctor to 1,200 inhabitants. Only in Manhattan is the proportion one to less than 500 inhabitants.

The great need is not more doctors, but better ones, and this need the Medical Society of the

State of New York is striving to meet in a two fold way. 1. By a system of graduate education conducted through the county societies, and, 2, by a happy understanding between the Medical Societies, the official Departments of Health, and the lay health organizations.

If the people of a community think they need a doctor, the lay health group, such as the County Committee on Tuberculosis and Public Health, is the proper organization to investigate the conditions and supply the lacking element. In most cases the real need is that for a public health nurse.

THE COMMITTEE TO INVESTIGATE CHIROPRACTIC

The last Legislature authorized the appointment of a committee of Senators and Assemblymen "To sit anywhere in the State and inquire into the nature and work of chiropractors within the State and their qualifications to perform the service rendered by them, and to propose such legislation as such committee shall deem necessary for the regulation and control of the practice of chiropractic in the State of New York."

The members appointed were Senators Karle of Queens, and Shackno of Bronx, and Assemblymen F. M. Smith of Otsego, Allen of Dutchess, and Reidy of Bronx.

The committee was given an expense fund of five thousand dollars, and was instructed to report on or before February 15, 1927.

It is to be hoped that the committee will make a real investigation of the methods used by chiropractors and will put them on record as to just what they actually practice and what is their attitude toward bacteriology and communicable diseases.

If the committee permits a dignified cross-examination of the chiropractic witnesses, the upholders of the cults will convict themselves out of their own mouths.

LOOKING BACKWARD—THIS JOURNAL TWENTY YEARS AGO

Twenty years ago the milk situation in the State was not so very different from that at present. The standards had been set, and had been adopted by the cities and ignored by rural districts, just as they are at present.

THE NEW YORK STATE JOURNAL OF MEDICINE for June, 1906, contains an article on "The Milk Problem" by Dr. W. A. Baker, Health Officer of the rural town of Islip. The following statement by Dr. Baker is as true and applicable today as it was in 1906:

"The task of inaugurating a system of this kind in a whole township is a difficult one, and would require strenuous and determined efforts. A large part of the public would be apathetic, and among the producers of milk you would find many who did not know, and could not, and would not be taught, many antagonisms would be aroused, and as Health Boards are at present constituted, with the ever present factor of politics, they could hardly be expected, in my opinion, to take action excepting in a case of pressing importance to meet a

public demand, and a public demand can only be brought about by educating the public to a realization of the whole subject, and to this end I think we have an "entering wedge" in the work that is now being done by our larger cities. City people are coming more and more to appreciate the fact that the purity of their milk supply is being guaranteed, and as they realize more fully what this means, not only to themselves but especially to their children, they will not only ask, when they go into the country for the summer months, but demand to know the quality of the milk that is offered to them. In other words, they will purchase only 'certified' milk."

The grade "Certified" milk has not had the general sale that Dr. Baker expected, because Grade A pasteurized has come to stand for a high standard of purity and wholesomeness. But even the label Grade A pasteurized milk is no guarantee of the sanitary quality of the milk, unless the producers and distributors are reliable.

It is rather surprising that a review of rural milk control made twenty years ago will apply at the present day.

MEDICAL PROGRESS

Surgical Treatment of Medical Diseases of the Abdomen.—John B. Deaver (*Therapeutic Gazette*, May 15, 1926, xlii, 5) observes that the classification of medical diseases of the abdomen as contrasted with surgical diseases depends, obviously, on individual opinion and experience. The unquestionably surgical diseases are pyloric obstruction, gastric tumor, chronic tuberculous ulcer of the intestine, acute appendicitis, chronic appendicitis, acute inflammations of the gall-bladder, acute pancreatitis, chronic interlobar pancreatitis in the presence of jaundice, and acute suppurative hepatitis. Patients with gastric and colonic ptosis are often made worse by operation, these cases are now wisely transferred to the medical realm. Colitis is strictly a medical condition, with the rare exception of the advanced ulcerative type. In adults in whom the differential diagnosis between appendicitis or appendicocolitis and appendicitis is impossible, removal of the appendix is required, followed by vigorous medical treatment of the diseased colon. Peptic ulcer and chronic inflammations of the gall-bladder are conditions which have excited much controversy. According to Deaver's experience, if the symptoms of peptic ulcer do not subside after four months' medical treatment, or if they return after a temporary lull, operation should be performed. Once a diagnosis of infection of the gall-bladder or of the bile ducts is established, surgical intervention is indicated. In biliary cirrhosis the best results are obtained by early drainage and splenectomy. The treatment of portal cirrhosis or Laennec's cirrhosis is strictly medical as is also that of tabetic crises, abdominal angina, and herpes of the abdominal wall. Obstructive or hepatogenous jaundice requires surgical intervention. In cases of hematogenous jaundice, where the spleen is at fault, splenectomy offers much in the way of cure, while in suppression or toxic jaundice surgery has nothing to offer. Subacute pancreatitis, in the form of localized hemorrhages, never requires surgical interference, and the same is true of chronic interacinar pancreatitis. The only cure for wandering spleen is splenectomy. In pernicious anemia, splenectomy, in some cases with an enlarged spleen and a good blood picture, has resulted in amelioration, but it has never produced a cure in these cases. Among the most striking results in splenic diseases is the cure or arrest of Banti's disease by biliary drainage and splenectomy. The advisability

of splenectomy in Gaucher's disease remains in doubt. In tuberculosis of the spleen, splenectomy followed by a suitable regimen offers the best chance. In chronic tuberculous peritonitis, simple exploratory laparotomy, which often suffices to arrest the condition, is not a panacea in the presence of obstruction from adhesions. Embolism and thrombosis of the mesenteric vessels are difficult of diagnosis but should be kept in mind in any case of acute abdominal catastrophe. The only hope in such cases is resection of the gangrenous bowel.

The Medical Treatment of Surgical Diseases of the Abdomen.—Hobart Amory Hare (*Therapeutic Gazette*, May 15, 1926, xlii, 5) declares that there can be no medical treatment of surgical diseases, nor can there be any surgical treatment of medical diseases. The determination as to whether a case is surgical or medical primarily rests with the medical man. He takes on a degree of responsibility that is continuous in many cases for many years, whereas the surgeon takes on responsibility only at the time of operation. There are subacute or chronic conditions in which it is quite possible that by rest in bed and suitable nonsurgical treatment the dangers and complications of surgical measures can be avoided. From the standpoint of the surgeon, chronic dyspepsia is a hall-mark of a gall-bladder or gastroenteric lesion, but every medical man knows that only a relatively small percentage of those who have dyspeptic symptoms require surgery. The results of surgery are not always perfect. For a long time after operation an abdominal scar may be hypersensitive, and post-operative adhesions may cause the patient discomfort greater than his original suffering, the more so as the shock of the operation and ether administration has rendered his nervous system hypersensitive. It is possible, for example, that the absence of a gall-bladder may not be compensated for by an adequate or hypertrophied sphincter of Oddi, and the bile drools continuously into the small intestine and regurgitates into the stomach, so that the last state of the patient may be worse than the first.

There is more medical treatment needed for surgical cases than surgical treatment for medical cases. The average surgeon is far too careless in the preparation of his patient. Too little attention is given to carious teeth and infected tonsils. As a result, pathogenic organisms from these sources are liable to

localize in the devitalized surgical area, or may be drawn into the respiratory tract during anesthesia. More care should be given to the mind and nervous system before operation and much more attention should be given to postoperative care. The surgeon should be acquainted with the drugs he uses. As an illustration the common delusion still exists that a teaspoonful of sodium chloride to a pint of water makes a physiological salt solution, whereas, depending upon the size of the spoon and how it is piled up, it may be hypertonic, hypotonic or isotonic, and if hypotonic or hypertonic to a sufficient degree it is practically equivalent to a poison. Hare questions whether in collapse of the lung if it is recognized early, it might not be advisable, since there must be a partial vacuum in the pleural cavity, to make this vacuum more complete by aspiration and so to re-expand the collapsed lung. He also calls attention to the disadvantages of the Trendelenburg postures in that it throws the abdominal contents against the diaphragm, preventing its free movement and interfering with circulation in the upper abdominal zone.

Visceral Pain and Referred Pain—In an address before the Oxford Medical Society, J A Ryle (*The Lancet*, May 1, 1926, cxx, 5357) endeavors to support the hypotheses (1) That there is a true visceral pain felt by the viscus (2) That visceral pain is due to an abnormal increase in tension of the muscular element in the wall of the viscus, this increased tension resulting either from contraction or from failure on the part of muscle fiber to relax adequately in the presence of increased intravisceral pressures (3) That visceral pain when occurring alone, or dissociable from attendant somatic pains, may be accurately localized by the patient (4) That referred somatic pain and tenderness, e.g., the viscerosensory reflexes, and the associated visceromotor reflexes, although they may accompany a severe visceral crisis of mechanical origin, more frequently express an inflammatory lesion of the viscus (5) That, when persistent, they invariably express organic disease of the viscus of an inflammatory kind. It is never suggested that normal physiological sensations peculiar to certain viscera, such as hunger, sensation of repletion, appreciation of states of fullness of the bladder and rectum, are referred to somatic tissues. It seems plain that the hollow viscera are endowed with the same sensibility, positive and negative, as the skeletal muscles, in other words, visceral sense is muscle sense. The majority of non-inflammatory visceral pains (unless they fall into the group of severe visceral crises) are but rarely accompanied by reflected superficial soreness, and it is generally agreed that pains of mechanical origin, such as ordinary

stomach ache, intestinal colic, renal and biliary colic, are deeply localized. The reflected phenomena of visceral disease are best demonstrated in association with the severe forms of visceral pain or in association with inflammatory disease. The arm pain of angina, the subscapular pain of cholelithiasis, and the testicular pain in ureteric colic are the classical examples of the former group, of the latter is the hyperalgesia of muscle-guarding found in appendicitis and chronic gastric ulcer. Reflected phenomena rarely accompany diseases of a functional kind, they are generally associated with local organic changes. Ryle further supports his hypotheses by detailed consideration of disorders of the stomach, the gall-bladder, the appendix, the intestine, the kidney and ureter, the uterus and fallopian tubes, and the heart and arteries. With reference to the latter he argues that angina pectoris is due to an increase in tension in the walls of the aorta or coronary vessels, or both depending not upon spasm but upon a failure to relax in the face of the increasing pressures and demands incident to increased cardiac work. There are eight reasonable questions which may be put in regard to visceral pain. These have reference to (1) situation, (2) extent, (3) character, (4) severity, (5) duration, (6) frequency (7) aggravating factors, (8) relieving factors. Inquiry should also be made concerning associated pains (deep and superficial) and other associated symptoms. There is still much to be learned by a careful study of pain.

Epidemic Encephalitis in China.—The impression among many physicians is that the so-called non-tropical sleeping sickness is virtually a new malady which prevails only in the more civilized races or at least that it practically does not occur in the primitive races. The position of the Chinese in the scale of civilization is difficult to fix, but the great body of this race lives under very primitive conditions. Until recently, judged by the files of the *Chinese Medical Journal*, the incidence of the disease in the country has not only been slight but more or less dubious. The first cases published were open to doubt. In passing it may be stated that the Parkinsonian syndrome is among the diseases not known to occur in China, so that its sudden appearance at this juncture could plausibly be ascribed to encephalitis. Dr M Pfister, neurologist of the Pekin Union Medical College, who supplies the above information in a communication appearing in the *Muenchener medizinische Wochenschrift* of April 16, 1926, has made an exhaustive study, extending over several years, to determine the exact incidence of the disease in his adopted country. The Pekin General Hospital records supply a measure of this incidence, and during the past two and one half years he has personally seen 100 cases, an analysis of which is

given In 1923 Woods, Pfister's predecessor in the same hospital, placed 21 cases on record. Over half of the cases were from the city and outlying country and the balance from various provinces. The earliest case goes back to 1919 and before its appearance at Peking there were still earlier ones at Shanghai and Foochow. Since 1921 cases have appeared annually at a summer resort much frequented by aliens. While 82 per cent of the author's 100 cases were in native Chinese the incidence in the relatively small contingent of whites was considerable, and as some of the Chinese had lived in close proximity to whites, the latter may possibly have transported the virus as carriers. The disease clinically is true to the European-American type.

The Hypotonic Symptom Complex — G. Joachim complains that while much has been written of hypertonic subjects with and without arteriosclerosis, but very little is said of the opposite or hypotonic group save the acute fall of pressure seen in collapse. With this he is not especially concerned here, and he confines his studies to cases of permanent low blood pressure, calling attention to the fact that subjects with the latter are somewhat inclined to fainting fits as part of the syndrome. In order to have a material basis for his conception of a low pressure subject, he has taken the blood pressure in 3,000 consecutive patients and in this number he found 181 with habitually low figures. Not all could be regarded as natural hypotonics for 19 had organic heart disease and 14 others were suffering from some form of cachexia — tuberculous, cancerous, Addisonian, etc. This leaves the constitutional hypotonics at 148 or about 5 per cent. The criterion was a systolic pressure below 110. In practically all cases the diastolic varied normally with the systolic, so that a hypotonic has a normal pulse pressure. In examining his 148 patients for symptoms and stigmata his results were inconclusive, unless we figure that what was obvious in the few was present to some degree in all. The author mentions only 10 per cent as actually showing sensible enlargement of the lymph nodes but seems to infer that this is a leading factor in the production of hypotonus, partly because extract of lymph glands has been found to possess a powerful pressor action in animal experiments. The energy of these subjects and their resistance to infections are small, they nearly all show a tendency to swoon under provocation, but little more can be said of the group as a whole. While some are of the asthenic build others have large frames and are stout, although pallor and pastiness are common. The condition is not to be confused with neurasthenia. The best remedy in theory and practice is strychnine. The author fails to allude to the relation between members of this group and persons with the status lym-

phaticus, who have enlarged lymph nodes and a tendency to sudden death — *Muenchener medizinische Wochenschrift*, April 16, 1926.

Radon Seeds in Carcinoma of the Tongue — In presenting a new technique of radium therapy in lingual carcinoma, Joseph Muir (*Annals of Surgery*, May, 1926, LXXIII, 5) discusses the advantages and drawbacks of the various methods heretofore used in the treatment of this condition. Imbedding of bare tubes according to Janeway's methods affords an even distribution of radiation, but causes necrosis, and may even induce unavoidable fatal hemorrhage. Screened tubes are objectionable because they must remain in the tongue as foreign bodies. The platinum needles advocated by Regaud obviate necrosis, as do the Janeway tubes, and can be removed when radiation is completed, but proper distribution of these applicators is very difficult, they cause much trauma, and above all they are hard to immobilize and cannot be placed on the posterior dorsal surface of the tongue. By limiting the amount of radium emanation employed in a single center to 2.5 millicuries, no evidence of necrosis has ever followed in any of Muir's implantations. The radon seed is so minute that its implantation causes little or no trauma. In making the application the growth is first carefully palpated, and the number of seeds required is determined according to its depth and surface extent. When a seed has been placed in the desired position, the attached thread is left protruding from the point of entry, where it is cut off so as to leave just enough to be readily grasped with forceps at the time of removal. It is not necessary to suture the seeds in place. The seed may be of any desired length, being radioactive throughout, so that its dimensions can be adapted to the length and breadth of the area to be treated.

Prophylaxis of Exophthalmic Goiter — Israel Bram, writing in *American Medicine* for April, 1926, XXI, 4, asserts that surgical attack upon the thyroid gland is resorted to, not because Graves' disease is medically incurable, but because there are few physicians who make sufficient sacrifice of time and energy to demonstrate perfect non-operative results. In the formulation of plans for the prevention of exophthalmic goiter it must be recognized that the future candidate for Graves' disease is of unique make-up, differing totally from the individual suffering from or susceptible to simple goiter. Physical and mental stimulation, expressed or implied, seems to dominate the existence of persons with potential or active Graves' disease. The fact that the present age is unnaturally stimulating explains why there are more cases of Graves' dis-

ease than ever before. In the interests of the prophylaxis of exophthalmic goiter the vital problem is how to raise the threshold of emotional reaction. The quality and quantity of education, food, sleep, occupation, home training, amusements, and many other factors require careful consideration and regulation. The desire for stimulation extends itself consciously or unconsciously toward food and drink, with perpetual whipping up of the sympathetic nervous system and the endocrines. These individuals should have little flesh food, and must abstain from condiments, spices, tea, coffee, and even certain soft drinks. Sleep must be of sufficient quantity and quality to be fatigue-dispelling—at least nine hours of restful sleep preceded by an hour of appropriate reading, conversation, or pleasant music. Nerve-racking occupations must be avoided. The author comments on the mad rush for amusements, and urges the cultivation, to take the place of emotional alertness, of the so-called phlegmatic temperament. The adherence to the broad principles of the simple life and the discovery and fortification of weak links in the subject's make-up will bring about the desired equilibrium in sufficient degree to be highly gratifying to all concerned.

Cure of Noma With Sulphate of Copper—F. Kaspar, writing in the *Wiener klinische Wochenschrift* of May 6, 1926, claims to have cured a case of noma by the simple use of a solution of copper sulphate. He was led to test this remedy because in his bacteriological work he found that it arrested the growth of Vincent's fusiform bacillus, now recognized as at least one cause of this dread disease. This one result he regards as sufficiently brilliant to report, but he has since learned that he has been anticipated in the use of the remedy by modern Russian physicians who have cured a considerable number of cases. The 10 per cent aqueous solution is used. Application of this solution to the gangrenous area of the cheek was followed in the author's case by the formation of a line of demarcation announcing that the disease process had been arrested. The author regards the Vincent fusiform bacillus acting alone as the cause of but one type of noma. In other cases the symbiosis of this organism with a spirochete appears to be the cause, and in this type the author fears that the copper solution might not cure as it has no power over the spirochete. Under these conditions he would add salvarsan locally and intravenously and would expect a cure. Salvarsan in turn has no power over the fusiform bacillus. The latter when it occurs in noma has an astonishing polymorphism and its simulation of other pathogenic bacteria has probably led

to reckoning some of these as able to cause the disease. As a matter of fact it is by no means unlikely that quite different organisms can produce the same gangrenous affection in the poorly nourished children who contract it. The author's patient chanced to be an adult, which is an extremely rare coincidence, for of 413 cases collected by Bruns only 11 were in individuals over 15 years of age. In the author's case and two others quoted by him, also in adults and both fatal, the noma followed extraction of a tooth. The mortality of the disease in the past has reached 80 per cent, but recent cases are showing an improvement on this figure.

Vaccinal Immunization of Newborn Infants Against Tuberculosis—Professor A. Calmette, chief of the Pasteur Institute, Paris, assisted by C. Guérin, L. Negre and A. Boquet, reports on the results of a five-year trial of the vaccine known as BCG. The summary is in part as follows. It has been shown that subjects free from any preexistent taint of tuberculosis may be immunized against both accidental and provoked bacillary infection not only by inoculation but also by buccal absorption. The vaccine is an emulsion of living culture which was originally of a virulent bovine strain but which has been deprived of certain qualities by slow and hereditary modification, using as a medium oxbile, which is naturally alkaline and rich in lipoids. The bacillus has been rendered avirulent while preserving its antigen properties. It is well tolerated by mammals and birds of all kinds and has never caused inoculation tubercle. The immunity is for a year and upwards in young bovidæ, various monkeys and anthropoids, while for laboratory rodents it is not so long. In regard to mankind it is not claimed that the vaccine will immunize adults or adolescents, save perhaps in countries not yet ravaged by the disease. The subjects must be sound and react negatively to the tuberculin test. Longer immunity may be secured by further inoculation or buccal administration, but obviously the amount of immunity derived by human beings can only be estimated indirectly. As the title of the paper implies the work has been limited chiefly to very young infants, and special emphasis is laid on the importance of including all sound subjects whose mothers are tuberculous. Over 5,000 nurslings have been vaccinated in the past five years and the actual mortality in this series from tuberculosis is about 2 per cent while the ordinary figures used for control are nearly 25 per cent. There have been no accidents nor untoward sequelæ of any sort from the vaccine and the method is recommended as quite harmless. *Annales de l'Institut Pasteur*, February, 1926.

given In 1923 Woods, Pfister's predecessor in the same hospital, placed 21 cases on record. Over half of the cases were from the city and outlying country and the balance from various provinces. The earliest case goes back to 1919 and before its appearance at Peking there were still earlier ones at Shanghai and Foochow. Since 1921 cases have appeared annually at a summer resort much frequented by aliens. While 82 per cent of the author's 100 cases were in native Chinese the incidence in the relatively small contingent of whites was considerable, and as some of the Chinese had lived in close proximity to whites, the latter may possibly have transported the virus as carriers. The disease clinically is true to the European-American type.

The Hypotonic Symptom Complex—G Joachim complains that while much has been written of hypertonic subjects with and without arteriosclerosis, but very little is said of the opposite or hypotonic group save the acute fall of pressure seen in collapse. With this he is not especially concerned here, and he confines his studies to cases of permanent low blood pressure, calling attention to the fact that subjects with the latter are somewhat inclined to fainting fits as part of the syndrome. In order to have a material basis for his conception of a low pressure subject, he has taken the blood pressure in 3,000 consecutive patients and in this number he found 181 with habitually low figures. Not all could be regarded as natural hypotonics for 19 had organic heart disease and 14 others were suffering from some form of cachexia—tuberculous, cancerous, Addisonian, etc. This leaves the constitutional hypotonics at 148 or about 5 per cent. The criterion was a systolic pressure below 110. In practically all cases the diastolic varied normally with the systolic, so that a hypotonic has a normal pulse pressure. In examining his 148 patients for symptoms and stigmata his results were inconclusive, unless we figure that what was obvious in the few was present to some degree in all. The author mentions only 10 per cent as actually showing sensible enlargement of the lymph nodes but seems to infer that this is a leading factor in the production of hypotonus, partly because extract of lymph glands has been found to possess a powerful pressor action in animal experiments. The best remedy in theory and practice is strychnine. The author fails to allude to the relation between members of this group and persons with the status lym-

phaticus, who have enlarged lymph nodes and a tendency to sudden death—*Muenchener medizinische Wochenschrift*, April 16, 1926

Radon Seeds in Carcinoma of the Tongue—In presenting a new technique of radium therapy in lingual carcinoma, Joseph Muir (*Annals of Surgery*, May, 1926, LXXXIII, 5) discusses the advantages and drawbacks of the various methods heretofore used in the treatment of this condition. Imbedding of bare tubes according to Janeway's methods affords an even distribution of radiation, but causes necrosis, and may even induce unavoidable fatal hemorrhage. Screened tubes are objectionable because they must remain in the tongue as foreign bodies. The platinum needles advocated by Regaud obviate necrosis, as do the Janeway tubes, and can be removed when radiation is completed, but proper distribution of these applicators is very difficult, they cause much trauma, and above all they are hard to immobilize and cannot be placed on the posterior dorsal surface of the tongue. By limiting the amount of radium emanation employed in a single center to 25 millicuries, no evidence of necrosis has ever followed in any of Muir's implantations. The radon seed is so minute that its implantation causes little or no trauma. In making the application the growth is first carefully palpated, and the number of seeds required is determined according to its depth and surface extent. When a seed has been placed in the desired position, the attached thread is left protruding from the point of entry, where it is cut off so as to leave just enough to be readily grasped with forceps at the time of removal. It is not necessary to suture the seeds in place. The seed may be of any desired length, being radioactive throughout, so that its dimensions can be adapted to the length and breadth of the area to be treated.

Prophylaxis of Exophthalmic Goiter—Israel Bram, writing in *American Medicine* for April, 1926, XXI, 4, asserts that surgical attack upon the thyroid gland is resorted to, not because Graves' disease is medically incurable, but because there are few physicians who make sufficient sacrifice of time and energy to demonstrate perfect non-operative results. In the formulation of plans for the prevention of exophthalmic goiter it must be recognized that the future candidate for Graves' disease is of unique make-up, differing totally from the individual suffering from or susceptible to simple goiter. Physical and mental stimulation, expressed or implied, seems to dominate the existence of persons with potential or active Graves' disease. The fact that the present age is unnaturally stimulating explains why there are more cases of Graves' dis-

FAILURE TO REMOVE STONE IN OPERATION UPON GALL BLADDER

In July a woman called at the office of a physician in the village in which she resided, complaining of pain in the right arm and right side. Examination disclosed an enlarged gland and an abscess, which was incised, cleansed and drained and which healed without any untoward event. In the latter part of July she again returned to the physician, at this time complaining of pain in her right side and nausea. Examination showed a tenderness in the region of the gall bladder and medical treatment was given for the condition. She again called upon the physician about the middle of August, and after examination the same condition was found except that she was suffering from increased pain and had been for several days. A few days thereafter the physician called at her home and upon examination he found that the condition had grown more severe. He then advised that she be operated upon by a surgeon in an adjoining city. On August 20th the patient entered the hospital and on August 21st the surgeon, assisted by the family physician, under a general anaesthesia, made an abdominal incision, drained and cleansed the gall bladder, finding no stones, but found the gall bladder infected. The gall bladder contained several ounces of a vitiated bile of a thick ropy nature. It was drained and cleansed and a drainage tube placed therein. The gall bladder was also found to be abnormally enlarged. While at the hospital the patient remained under the care and attention of the operating surgeon, who cleaned, drained and dressed the wound almost daily. She remained at the hospital until September 8th, at which time her husband gave notes to the surgeon for his services. On December 6th a partial payment was made upon one of the notes and the note renewed. No further payments were made to the surgeon for any services rendered by him. After leaving the hospital the patient was not attended by the surgeon except on December 6th when she called at his office to make the partial payment and to renew the note, he talked with her with reference to her condition, but made no examination nor did he render any treatment.

After returning to her home from the hospital she was treated by the family physician upon various days between September 12th and November 24th, at each of which times the gall bladder was thoroughly cleansed and antiseptic dressings applied. She was also furnished with antiseptic dressings and instructed as to the dressing of herself between her calls upon the family physician. She did not return to this physician after November 24th. The physician and surgeon learned that the patient had gone to a surgeon in another city, who operated upon her and removed a smooth stone from the gall bladder.

A few months after the performance of the second operation both the patient and her husband instituted actions against the family physician and the surgeon who had first operated upon her, charging that the defendants negligently made an incision into the patient's abdominal cavity but did not remove from plaintiff any gall stones, which the defendants claimed caused the plaintiff's illness, and that the defendants negligently failed to complete the operation and failed to remove the gall stones, and that by reason of their negligence the plaintiff was not cured of her malady of gall stones and was required to submit to a second operation for the removal of such gall stones and was rendered sick and incapacitated for a long period of time. The answers of the defendants denied any negligence upon their part in their examination, diagnosis, treatment or operating upon the plaintiff. The answer of the surgeon set up as an affirmative defense that any cause of action against him was barred by the statute of limitation, as he had treated the plaintiff only between the 20th of August and the 8th of September, and that the action against him had not been instituted until four days after the two-year statute of limitation had run on an action against him for malpractice.

When the case came on for trial the plaintiffs testified in their own behalf and gave their version of the examination, treatment and operation by the respective defendants, and as to the defendant surgeon it was claimed that at the time she called upon him on December 6th he examined and treated her. The plaintiffs also called as a witness in their behalf the surgeon who performed the second operation, but his testimony was not sufficient to establish, by the finding and removal of the gall stone by him that it was present at the time the defendant surgeon operated, or if present, that the failure to remove the same was due to any negligence or carelessness in the performance of the operation. At the close of the case the trial court dismissed the complaint on the merits as against the family physician, and as against the defendant surgeon dismissed it on the ground of the defense of the statute of limitation, holding that the relation of physician and patient had terminated on September 8th and was not continued or renewed by the plaintiff's call on the surgeon on December 6th, when she made an installment payment upon the monies due the surgeon for his services. After the entry of judgment in favor of the defendants the plaintiffs served a notice of appeal to the appellate court and prepared and served the record on appeal. Thereafter and before the argument of the appeal, the entire matter was disposed of by the withdrawal of the appeal, the discontinuance of the actions and the exchange of releases by all parties.

LEGAL

By LLOYD PAUL STRYKER, Esq
Counsel, Medical Society of the State of New York

THE DOCTOR CARRIES ON

Nothing more fitly symbolizes the pluck and the determination of the soldier to go forward than the terse two-word order Carry on! Into this short command there is packed the whole language of courage and patriotism

As we stand day in and day out before courts and juries battling for the rights of accused doctors, and as we study and apprehend the fine morale and the splendid service of the medical profession—often under attack, frequently misrepresented, many times assailed and seldom fully understood—it has occurred to us more than once that there is no body of men that more loyally obeys the command "Carry on!"

Little does the public know of the vast amount of uncompensated work in the alleviation of pain, sickness and disease that is "carried on" by the medical profession. Perhaps there is no single fact which more sharply differentiates modern times from antiquity than the patient, quiet, unheralded, unrequited and generous service which doctors give to the poor patients in our great hospitals and elsewhere. Men, women and children who cannot afford to pay either for medical care or nursing are treated by physicians with the same care and skill, the same zeal, the same loyalty and the same enthusiasm as are the patients who are able to pay. Diagnoses are made of the most elaborate and thorough character involving radiography, bacteriology, clinical findings, and the manifold agencies which the physician enlists in determining the nature and cause of a disease. Treatments and remedies are given, fractures are reduced, operations are performed, after-care is administered, daily to thousands of poor people who could not possibly secure these things if the physicians did not give of their time, their skill, their knowledge and their experience without stint and without reward of any kind, save the compensation which comes from the consciousness of having performed a service to mankind. Although, of course, endowed institutions, societies for medical benefit, life insurance and analogous bodies are not entitled to receive such service, the medical profession, to a man, is loyal to the mandate of its twenty-seventh principle of professional conduct "Physicians should always recognize poverty as presenting valid claims for gratuitous services."

Perhaps far more than the clergyman, the doctor and the lawyer have opportunities for the study of human nature. It is a study more fas-

cinating, more educational than that which could be derived from books. Fortitude is seen, courage, generosity, appreciation and unfortunately the absence of these is also frequently discovered. The real and true expression of gratitude by a patient oftentimes is a greater reward than financial compensation, but there is nothing more discouraging, more depressing or embittering than a lack of gratitude for professional work well done. And yet how often is this the sole reward of the doctor who has labored, who has worried and who has borne the burden and heat of the day in a valiant contest against disease or death itself.

As we have sat through the long hours in court and have listened while the opposing lawyer pilloried and assailed an honorable and an innocent doctor and held him up in the presence of the court and jury and the curious spectators to ridicule and contempt, we have often marveled at the equanimity and the patience with which these things are borne by the worthy doctor. How many times have we seen the doctor who has done all that science could do, who possesses all the qualifications that the law requires, who has kept abreast of the times in his study and has brought his manifold equipment to bear, find that when he has finished with his work his reward is the defense of a malpractice action. Time and again we have defended cases where what the doctor did had saved the patient's life, and yet the gratitude of that patient and of his friends was expressed in engaging a lawyer to pillory and assail the reputation of that doctor and, through their testimony, seek from him heavy money damages.

It requires philosophy, tolerance, sweetness of disposition, patience and forbearance to suffer these things and not to become embittered against human nature itself. The doctor who has been wounded by these "slings and arrows of outrageous fortune" the next day begins his work again and continues to minister to the sick, to treat and prescribe for those who are wholly unable to pay him for his services, knowing that when he is through his sole reward may be an unjust defamation of his character. There is something fine and strong in the heart and mind of the true physician who, under all these difficulties and dangers, "carries on."

Carry on! That is the slogan of the doctor in peace as it is of the soldier in war.

MONROE COUNTY MEDICAL SOCIETY

The regular meeting of the Medical Society of the County of Monroe was held at the Monroe County Tuberculosis Sanatorium on June 8, Dr A G Morris, president, presiding

Minutes of meeting of 16 March 1926, read and approved

Report of meeting of Comitia Minora read and approved

Election of candidates

Dr Morris appointed Drs Leve and Avery as tellers, who reported, after the balloting, Dr Ezra Bridge unanimously elected to membership

Reports of Committees

1 Periodical Health Examination

Dr Sawyer urged the members to cooperate by being examined

2 Legislative

Dr W A Calihan spoke of the success of legislation in the last session of the Legislature, and offered the following

"Resolved, That the secretary of this society be instructed to write a letter to each of the Legislators in this county who voted favorably on the Webb-Loomis Medical Practice Act Amendments in the last Legislature, expressing the appreciation of the Medical Society of the County of Monroe for their efforts to protect the public health of the State

And be it further resolved that the secretary write a letter to

1 The president of the Tuberculosis and Public Health Association, expressing to that organization, through him, our appreciation of their cooperation in presenting the problem of the Medical Practice Act to legislators and lay public in a way which helped materially in the passage of this legislation, citing particularly the active and thorough work of Mr Raymond Greenman, executive secretary

2 Mr Roland B Woodward, Secretary of the Rochester Chamber of Commerce, extending to him the appreciation of this organization for the active efforts which he put forth in the furtherance of the passage of the Medical Practice, citing in this letter the very fine cooperation given by Miss Bingeman

3 Mr Percival D Oviatt, who as a representative of the Chamber of Commerce, gave up a day to be present in Albany at the hearing before the Governor, expressing to him our sincere appreciation of his cooperation"

Dr Calihan moved the adoption of this resolution

Seconded and carried unanimously

Dr Wolff moved that a vote of thanks be extended to Dr W A Calihan, chairman, and the other members of the legislative committee for their efficient work in behalf of the Medical Practice Act

Seconded and carried unanimously

Dr Winslow read a letter from Dr Burton Simpson, relative to the placing of the State Institute for the Study of Malignant Disease at Buffalo, N Y, under the jurisdiction of the State Health Department, and moved the adoption of a resolution urging its transfer to the control of the State Board of Charities

Seconded

The secretary read a letter from Dr Matthias Nicoll, Jr, Commissioner of Health, re this matter

Moved by Dr W A Calihan that the matter be laid on the table

Seconded and carried

The secretary read a letter from Dr G A Goler, Health Officer, relative to the Health Department's plans for toxin anti-toxin campaign

Discussed by Drs Johnson, Hazen and N W Soble

Program—Scientific

"Symposium on Pulmonary Tuberculosis"

Dr Ezra Bridge "Interesting possibilities of expiration and cough"

Dr H P Smith "Tubercle in the lung" (with pathological slides)

Dr Joseph Green "Differential Diagnosis of Diseases of the Chest, by the Roentgen Ray" (with slides)

Dr A M Stokes "What the Monroe County Tuberculosis Sanatorium does for its cases"

Scientific Program

The symposium was given by members of the Sanatorium Staff, Dr Bridge, Superintendent, Dr Stokes, Resident Physician, Dr Smith, Pathologist, and Dr Green, Roentgenologist

Dr Bridge gave a very enlightening demonstration on a patient of the practical advantages of the expiratory cough, and the proper manner of using this aid in examination

Dr Stokes summarized very closely the routine of the Sanatorium and the most effective and approved methods in use in the treatment of the various phases of tuberculosis

Dr Smith showed a number of excellent pathological slides and specimens

Dr Green demonstrated a large series of interesting and instructive X-ray slides, bringing out very clearly the differential points of diagnosis of diseases of the chest, from an X-ray standpoint

Discussion by Drs Lloyd, Richard, Davidson, Soble and Bridge

Dr C R Barber, of the Board of Managers of the Sanatorium, invited the members to partake of a very enjoyable lunch as the guests of the Sanatorium

NEWS NOTES

THE CONTROL OF X-RAY LABORATORIES

The use of the X-ray for the diagnosis and treatment of human beings may be a grave menace to health and is, therefore, a public health problem. The Department of Health of New York City has, therefore, incorporated the following regulations in its Sanitary Code

Section 107 No person shall maintain, operate or conduct an X-ray laboratory or advertise or hold out to the public that an X-ray laboratory is maintained, operated or conducted, wherein radiographs are taken, diagnoses made or human beings examined or treated by X-rays, without a permit therefor issued by the Board of Health, or otherwise than in accordance with the terms of said permit and with the Regulations of the said Board. (As adopted by the Board of Health, January 26, 1922)

Regulations Governing the Conduct and Maintenance of X-ray laboratories in the City of New York (Adopted by the Board of Health, January 26, 1922)

Regulation 1 Information to be furnished by applicant. Every applicant for a permit to conduct an X-ray laboratory shall be made in writing on an official blank to be furnished by the Health Department and must contain the following information

Location of building
Location in building
Character of building
Name of owner of building Address
Name of applicant Address

If a corporation

- (1) When and where incorporated
- (2) In what county certificate has been filed and date filed
- (3) Officers of the corporation.

- (4) Place of business of the corporation.
- (5) Full and accurate incorporate name

If a partnership

- (1) Names of persons composing partnership in full, with their places of residence

If a trade name

- (1) The full names of the person or persons doing business under such trade name.
- (2) Complete and full trade name
- (3) Place of filing of certificate as required by the statute, and date filed

Regulation 2 A duly qualified person to be in charge. Every X-ray laboratory shall at all times be in charge and under the direction of a duly licensed physician or other person who is licensed under the Laws of this State to diagnose and treat diseases and whose knowledge, experience and qualifications to operate and use an X-ray machine are satisfactory to the Health Department. (As amended by the Board of Health, Feb 6, 1926)

Regulation 3 Precautions against danger. Every X-ray laboratory shall be so constructed as to confine within the operating room the rays emanating from the machine and it shall be equipped with suitable and necessary appliances and devices at all times when the X-ray machine is in operation for the proper protection of patients, operators and all other persons or property adjacent, contiguous to or coming in contact with the electrical or other current or force or spark generated or incident to the operation and use of the X-ray machine

Regulation 4 Permits may be revoked in the discretion of the Board of Health

Regulation 5 No permits shall be transferable as to the person or place. A permit is issued to a particular person, firm or corporation and for a given location and is not valid for use by any other person or in any other place than stated in the application for a permit

THE MEDICAL SOCIETY OF THE COUNTY OF ONEIDA

The regular meeting of the Oneida County Medical Society was held on Tuesday, April 13, 1926, at Utica, N Y, with a large attendance. Dr J Lloyd Golly, of Rome, President of the Society, occupied the chair

In addition to the election of Dr Melvin G Preston, of Utica, and Dr L S MacMillan, of Taberg, as members of the society, and Dr E W Huxtable by transfer from the Wayne County Medical Society, we had reports from the Delegates to the House of Delegates. Dr Andrew Sloan, for the Delegates, announced the election of Dr G M Fisher as President of the State Society, also the election of Dr T H Farrell as Delegate from the Medical

Society of the State of New York to the American Medical Association. Dr Sloan let it be understood that the Delegates from Oneida County were well occupied with executive and committee room work during the recent session of the House of Delegates

Scientific Program of the meeting consisted of an address by Dr George E Beilby, of Albany, N Y, on "The Indications for Surgical Treatment in the various types of goitre with an analysis of results," which was immensely appreciated by all present, and discussed by a number of members, including Drs Evans, J D Jones, Guile and Smith

ULSTER COUNTY MEDICAL SOCIETY

The regular meeting of the Ulster County Medical Society was held in the Governor Clinton Hotel, Kingston, New York, on June 3, 1926, at 8 30 o'clock, with the president, Dr Mary Gage Day in the chair. Three new members were elected, Dr W P Van Wagenen, Lake Mohawk, Dr W S Bush, Atwood, N Y, and Dr J C Gross, Phoenicia.

The principal feature of the meeting was a testimonial dinner to the physicians of Ulster County who had practiced medicine for fifty years or more. These were

Dr J R Nelson, Kingston, Dr A P Chalker, Kingston, Dr Henry Van Hoevenberg, Kingston, Dr E H Loughran, Kingston, Dr George C Basten, Kingston, Dr B F Neal, Ellenville, Dr R Crawford, Saugerties.

The toastmaster was Dr Laughran, who described an epidemic of smallpox in the vicinity of Kingston in 1872. He had worked on the epidemic five months and then had taken the disease and was quarantined in the "Pesthouse" in the woods with a number of folks, both white

and colored, and according to his opinion now they "had a bully good time."

Dr Crawford told of the trial, fifty years ago, of the man who shot Jim Fisher. Dr James R. Wood, the famous surgeon, testified that when he could not locate the bullet with a probe, and had inserted his finger into the abdomen, the lawyer for the defense claimed that, since it was recognized that to enter the abdominal cavity was fatal, Dr Wood was the real murderer.

Dr Chalker said that in his younger days an old doctor of Kingston carried a big box on the rear of his buckboard with which he put the chickens and pigs that he received as fees.

Dr Van Hoevenberg recalled the days of his father and grandfather, both of whom practiced medicine in Kingston. His father had given the first chloroform anesthetic in Kingston, and his grandfather was an army surgeon in the war of 1812.

Dr Nelson said his father and uncle were doctors, and his mother, who was the daughter of a clergyman, read a chapter of the Greek testament daily in the original Greek.

CLINICAL CONGRESS OF THE CONNECTICUT STATE MEDICAL SOCIETY

The second Clinical Congress of the Connecticut State Medical Society is scheduled to meet on the three days in September 21 to 23, in New Haven. Practical papers will be given during the day. One evening will be given over to a symposium on the Periodic Health Examination and another to a smoker. A fee of ten dollars will be charged, but it will include the smoker and a luncheon on each day of the session, parking space and garage for a car, and a copy of the printed abstracts of the papers—surely a modest fee.

The Clinical Congress of the Connecticut State Medical Society is in its second year. The activity was started last year by a group of men here in New Haven who wished to promote a post-graduate assembly. It was first contemplated to do it independently, but upon further consideration it was deemed advisable to have it under the patronage of the State Society. The Congress last year was very successful and this year seems to

promise even more. It is not the annual meeting of the Society, as a matter of fact it is not any stated meeting of the Society, it is simply a post-graduate assembly arranged for the physicians of Connecticut and neighboring states. It finances itself. The gentlemen who direct its activities are of necessity all members of the State Medical Society, but the President of the Congress is not the President of the State Society, and he appoints his committees to carry on the work. There is finest harmony between the management and the Council of the State Society. Two of the eight Councillors are on the Executive Committee of the Congress.

Last year three hundred and fifty doctors were present from six states. This year five hundred are expected. Physicians from New York State are cordially invited to attend. The Secretary of the Congress is Milton C. Winternitz, M.D., Dean of the Medical School of Yale University.

MEDICAL SOCIETY, COUNTY OF QUEENS

A regular meeting of the Medical Society of the County of Queens was held Tuesday evening, April 27, 1926, at Eagle Palace, Jamaica. President Dr. Denis McMahon in the chair.

The minutes of the meeting of April 6, 1926, were read and approved as amended.

The chair announced that with the consent of the society the usual order of the program would be reversed, whereupon the society proceeded with the Scientific Program.

1 Paper The X-ray Diagnosis and Treatment of Tumors of the Mediastinum, with lantern slides, illustrations of X-rays of such tumors—John G. Williams, M.D., Brooklyn.

The speaker described the various types of tumors, the frequency of their occurrence, the value of the X-ray in conjunction with the clinical features in the diagnosis. Among other things *he emphasized the more favorable response to X-ray therapy of malignant tumors and the value of such improvement in the differential diagnosis, and the results of treatment, with presentations of cases.* Discussion by Drs. Thomas, Voltz, Lesoff, Startz, and closed by Dr. Curran.

2 Talk—Surgery of Accessible Neoplastic Diseases by Endo-thermy. Slides and Motion Pictures—George A. Wyeth, M.D., New York.

The speaker used the term endothermy as the surgical application of high frequency currents, in contra-distinction to the term diathermy, indicating the medical applications of high frequency currents. Before proceeding with destruction of the malignant tissue, it is first surrounded by a layer of coagulated tissue by which the lymphatics and blood vessels are closed, preventing migration of malignant cells and diminishing the tendency to metastases.

The use of the mono-polar and bi-polar current methods and the endothermy knife were explained.

Discussion by Drs. Thomas, Lesoff, Davis, Getler, Lint, closed by Dr. Wyeth.

On motion by Dr. Langer a vote of thanks was extended to the speakers of the evening.

Executive Session

For the Comitia Minora, Dr. Dobbins moved the election of George A. Irwin, M.D., 109-19 Farmer's Avenue, Hollis, L.I., Louis G. Raff, M.D., 45-30 National Avenue, Corona, L.I., Hyman Rappaport, M.D., 168 Forty-sixth Street, Corona, L.I. By one ballot cast by the Secretary, motion seconded and passed, whereupon the chair announced the candidates members of the society.

Dr. Berry, Chairman of the Legislative Committee, reported the fates of the various bills considered by the State Legislature and moved that the President be instructed to send a message to the Governor that our society disapproves the Webb-Loomis bill and ask him to veto it. The motion was passed by a vote of 37 to 8.

Dr. Whelan reported for the Membership Committee.

Public Health Committee—no report.

A letter from the Medical Society of the County of Niagara to the President of the Society was read by the Secretary, requesting the Society to endorse Niagara Falls as the next meeting place for the annual meeting of the State Society. On motion by Dr. Thomas, duly seconded and passed, the society resolved so to act.

Under new business, it was announced that the proposed amendment to the By-Laws relative to Trustees had been referred to the Committee on Revision of the By-Laws, to which Dr. Flemming, the mover of the amendment, had been added.

Dr. Flemming spoke on the matter of the formation of the Library Association. The matter was referred back to the special committee.

Dr. Flemming announced that the Queensboro Tuberculosis Association would like to broaden its field of work and change its name to conform to such broader field of work and moved the adoption of the following resolutions.

Whereas, The records of the Department of Health of the Borough of Queens show that the number of deaths from Heart Disease vastly exceeds any other cause of death in this Borough, and,

Whereas, The figures for Maternal Mortality complicating childbirth continue unnecessarily high, and,

Whereas, The experience of physicians especially skilled in the treatment of these diseases is that many of the conditions causing such deaths may be recognized sufficiently early to be at least controlled, and,

Whereas, The Queensboro Tuberculosis Association through its change of name to the Queensboro Tuberculosis and Health Association has indicated its desire to broaden the scope of its activities for the prevention of disease and the promotion of health.

THEREFORE BE IT RESOLVED, That this Society recommend that the Queensboro Tuberculosis and Health Association undertake an educational campaign for the prevention and control of Heart Disease and Maternal Mortality among the citizens of this Borough, through earlier and more adequate care by the Physician of each patient's choice, and,

BE IT RESOLVED, That this Society offers its hearty cooperation in such work.

Resolutions seconded, unanimously passed.

Dr. Prest announced the coming talks of the Graduate Education activities, especially emphasizing the talks of Dr. Kolb.

The President announced the plans for the Outing Meeting in cooperation with the Medical Society of the Greater City of New York.

Attendance, 52.

Adjourned.

PREVENTION OF EARTHQUAKE DISASTER

The reports of recent earthquakes in the Grecian Islands has directed attention to the possible effects of a severe earthquake on Manhattan Island

The *Tribune* of June 28 carries a reassuring editorial, which is as follows

EARTHQUAKE PREPARATION FOR NEW YORK

Several of our correspondents have been perturbed by the erroneous report in one of our contemporaries that the Board of Trade and Transportation had omitted from its survey of New York's preparations for emergencies the one emergency which is probably the only real danger of widespread disaster which New York needs fear. This is a disaster by earthquake. Fortunately, this peril has been included in the survey.

It is true that New York City does not lie in an earthquake zone. Dangerous shocks are by no means so likely here as in Japan or California or Italy or other places where the subterranean forces remain exceptionally vigorous. But no spot on earth is totally free from earthquakes. The eastern coast of the United States experienced severe shocks in Colonial times. Even the Charleston earthquake of the '80s was by no means insignificant. While alarm about an earthquake hazard for New York is by no means justifiable, neither is it proper to neglect this hazard altogether when city-wide plans are made to meet emergencies. No geologist doubts that, sooner or later, New York City will feel a considerable earth tremor. The shock will almost certainly not be disastrous, provided the city is prepared.

The most important item of preparation—probably the only important item—is one of public education. No earthquake is likely to harm our tall buildings. It has been proved by Japanese and Californian experience that such structures resist earth shocks exceptionally well. Nor is there any serious danger of uncontrollable fire or of irreparable damage to the water supply such

as occurred in San Francisco. The real earthquake danger of New York City is that of panic.

A disturbing earth shock occurring during business hours would spill millions of panic-stricken individuals into the streets. There are sections of the city where this would jam the street area more than one person deep. A shocking catastrophe far transcending any fire panic would be almost inevitable. There is just one way to avoid this. It is to drive home to all New Yorkers, in advance, the idea that an earthquake panic is useless and avoidable to tell them, over and over again, that the safest place during an earthquake is inside a steel-and-concrete office building. If even half the people believe this and act accordingly a street panic will be avoided, and a shock, even a severe one, will do us relatively little harm.

On the evening of June 28 the *New York Sun* carried an article entitled "Devils Mobilize for War on Man." The occasion is a warning issued by a conference of spiritualists assembled in London. The description says

H. J. Strutton, editor of the *Occult Review*, committed himself to paper in the latest prediction

"The visions of seers and the conclusions of the students of prophecy," he says in an article, "all point to the end of 1926 as witnessing the culmination of the present cycle of madness, the climax of a period of increasing chaos, and the ushering in of an era of destruction."

"In the end," he declares, "civilization will be saved from utter destruction only by the visitation of some devastating seismic catastrophe that will shake the warring nations out of their madness and compel them to call a halt."

There seems a slight ray of hope, for it is hinted that if "enough people enlist on the side of the angels" within the next two years they may be able to give the devils a fight and eliminate earthquakes.

BANANA SEED

A marked improvement of a food may have a great effect on diet, and therefore on health. The banana has hitherto resisted attempts at improvement, because it could be propagated only from cuttings or roots only. But the *New York Sun* of July says that the seed has been discovered by Dr. F. J. Harris, of Florida, who is quoted

The pistillate or female flowers are at the base of the bunch, which, when it assumes the usual inverted position, places the staminate or pollen bearing flowers below, these are

found under the bracts of the tassel-like appendages. Then again the male flowers are not open until the female flowers of the same bunch are over and dead (one of nature's devices to bring about cross-pollination). But, since the pollen grains are not wind borne but are sticky and remain attached to the anthers.

The minute black specks sometimes found in bananas are unfertilized ovules upon the central placenta, the fertile seeds are three-eighths of an inch in diameter."

THE DAILY PRESS

CAUSES OF DEATH

Statistics may be either dry and uninteresting, or they may be highly emotional and poetical, according to the manner of their presentation. The New York Times of June 5 contains an editorial entitled "The Four Horsemen," which takes a middle course between the statistical and the poetical in the interpretation of the figures of the four greatest causes of death throughout the world. "The Four Horsemen" are poetical personifications of the causes of suffering and death as set forth in the sixth chapter of Revelation. The first rider was a bowman upon a white horse, and represented the selfish conquerors of the earth. The second sat upon a red horse and represented war. The third rode a black horse and carried a pair of balances with which he weighed out property as if it were the most valuable thing on earth—"See that thou hurt not the oil and the wine," said the rider. The fourth rider sat on a pale horse, named Death, and "Power was given unto him over the fourth part of the earth to kill with the sword, and with hunger and with death (pestilence) and with the beasts of the earth (accidents and natural causes, so-called)." .

We are accustomed to think of the book of Revelation solely as religious poetry, but its statistical facts are surprisingly true. War, famine, pestilence, and storm have always formed the greatest quartet as destroyers of human life, and they are still the four destroying horsemen.

It would seem to many that three of the four horsemen have been overcome, and that war, famine, and pestilence can be prevented, and that storms and other cataclysms of nature could be foretold and their effects minimized. But such a happy result has not yet come to pass. The woes of the Book of Revelation are still threatening, and it is equally true that its promises of a new heaven and a new earth are slowly being fulfilled. A clear diagnoses of the causes of human woes will inevitably lead to their amelioration.

The editorial in the New York Times quotes an authoritative study made by the Assistant Director of the Red Cross Societies. It says:

"War, pestilence, famine and cataclysms of nature have taken toll of 62,000,000 human lives since the outbreak of the World War. This is the estimate advanced on Thursday at Washington by the Assistant Director of the League of Red Cross Societies. By categories war has accounted for 9,000,000 lives, civil war for 6,000,000, famine for 6,000,000, epidemic for 40,000,000, and earthquake and flood for 2,000,000. The

uneasy conscience of mankind, seeking for an alibi, may stress the fact that two-thirds of the grisly harvest has not been the work of man, though he certainly did his bit in accentuating the effects of famine and disease."

There were 50,000 United States soldiers killed in the World War, but during the period of the active participation of the United States in the war, ten times that number of American people died from influenza.

The toll of influenza deaths in New York State for the year June, 1918, to June, 1919, is given on page 93 of the August first number of the Official Bulletin of the New York State Department of Health. The normal number of deaths from influenza and pneumonia for the period would have been about 20,000, but the actual number was about 70,000—an excess of 50,000, or the number of soldiers of the entire United States killed in battle.

The great argument against war is that it means death for a large number of citizens. Yet the studies of the Red Cross Director show that the World War caused less than one-third as many deaths as epidemic, and earthquake, and flood during the same period. The figures given

War	12,000,000
Epidemic	40,000,000
Earthquake and flood	2,000,000

The figures are the more striking because pestilence was not associated with the armies in the World War, but on the contrary, the armies were largely free from epidemics while civilians in quiet life were slain by the tens of thousands. The editorial says:

"First in rank among the visitations of nature has been the influenza, the secret of which is still to be traced and mastered. It has been estimated that between May, 1918, and March, 1919, the 'flu' took 25,000,000, or not far from 2 per cent of the entire population of the world. In India it has been deduced from the results of the census of 1921 that between twelve and thirteen million people must have perished during the epidemic. Entire regions in Africa were swept clean of life, and one can only conjecture what the death totals were in the interior of the continent, concerning which no definite information is available. In the United States the deaths in 1918-19 were nearly 550,000, and the total for the five years up to 1923 has been estimated at 750,000. The outbreak of 1922, though less virulent, took nearly 17,000 lives in Great Britain during the first three months of the year."

taught to recognize the symptoms, nor how they may spare the time from their multitudinous duties for physical examination of children

The prevention and control of school diseases is evidently a problem the solution of which requires the co-operation of all school elements and especially the joint action of medical school inspectors, school authorities and parents

G M P

CHEMICAL PATHOLOGY Being a Discussion of General Pathology from the Standpoint of the Chemical Processes Involved. By H. GIDEON WELLS, Ph.D., M.D. Fifth Edition. Octavo of 790 pages. Philadelphia and London, W. B. Saunders Company, 1925. Cloth, \$8.50.

H. Gideon Wells's book on "Chemical Pathology" has now reached its fifth edition, which fact alone serves to indicate its great value. It discusses pathology from a viewpoint that is becoming more and more important, namely, the chemical one. Only the future can decide just how important chemical pathology is and particularly its relationship to pathological anatomy. As the author comments in his preface much theoretical consideration has been included, the purpose being to stimulate investigation of all problems that so vitally concern the clarification of disease processes.

The work includes many sterling chapters. The one on "Pathological Pigmentation" being an exceptionally good one. Special attention must be called to the chapter on "Lipoids," which is occupying so much space in European literature.

The book is put together in a manner that is very complimentary to the publishers. As a whole, no medical library is complete without it.

S. R. SLATER.

GYNÉCOLOGIC UROLOGY By LYNN LYLE FULKERSON, A.B., M.D., F.A.C.S. Octavo of 247 pages with 166 illustrations including 86 original and 14 color plates. Philadelphia, P. Blakiston's Son and Company, 1925. Cloth, \$6.00.

This small book of 227 pages is of value because of its title as it calls to the gynecologist's attention the need of a knowledge concerning those organs so intimately connected with his more restricted field. The book is well written and well illustrated but many conditions, peculiar to women are not mentioned while some conditions, such as ptychitis of pregnancy should be dwelt with more exhaustively.

Despite some omissions this book can be well recommended.

G W P

A MEDICAL FORMULARY By E. QUINN THORNTON, M.D. 12th Edition, revised. 16mo of 352 pages. Philadelphia and New York, Lea and Febiger, 1925. Cloth, \$2.50.

This is an ideal book for the general practitioner who desires an up-to-date formulary. This revision conforms with the many changes made in the United States Pharmacopoeia Tenth Revision which alone recommends it to the thoughtful physician who wishes to prescribe scientifically and not according to the dictates of proprietary concerns who emphasize their products as superior to those of the Pharmacopoeia.

The author has been painstaking in introducing changes that have taken place in recent years in the treatment of Diabetes Mellitus, Syphilis, Scarlet Fever, Rhus Poisoning, Typhoid, Gastric and Duodenal Ulcers etc. making it valuable in this respect to those who wish a brief resume in these advances. The diseases are arranged alphabetically and the indications for the use of each formula is also an added feature.

FREDERICK SCHROEDER.

A SYSTEM OF CLINICAL MEDICINE. Dealing with Diagnosis, Prognosis, and Treatment of Disease for Students and Practitioners. By THOMAS DIXON SAVILL, M.D., Lond. Seventh Edition. William Wood & Company, New York, 1925. Price, \$9.00.

The seventh edition of this English book under the editorship of the widow and assisted by such men in English medicine as Rolleston, Patterson and Langdon Brown is really clinical.

The scheme followed and originating with the author in presenting the subject is the tracing of symptoms, relating to a part or organ in the order of common occurrence to their causes. Symptoms and physical examination are emphasized, etiology, pathology and treatment have appropriate sections. The laboratory aid is not discarded but so given that one may know what is essential to ask or look for—something of extreme importance in this day of too frequent routine laboratory quests where often a complete blood chemistry is simply a wild stab and hope that something will turn up.

Excellent chapters are given to female diseases—the skin and nervous system—again, all extremely practical—and adding materially to its clinical value.

The author simply makes the book interesting and at times fascinating. It is the type of book that could not be written by anyone who was not himself an eminent clinician.

HENRY WOLFER.

DISEASES OF INFANTS AND CHILDREN. By HENRY DWIGHT CHAPIN, A.M., M.D., Consulting Physician, New York Post Graduate and Willard Parker Hospitals, and Lawrence Thomas Royster, M.D., Professor Pediatrics, Pediatric Department of the University of Virginia. Fifth revised edition. William Wood & Co., New York, 1925. Price, \$6.00.

This is the fifth edition of the work originally written by Chapin and Pisk. Dr. Pisk's death required a new associate and therefore Dr. Royster collaborated with the senior author in the present edition. This work has been enlarged and rewritten so as to bring it thoroughly up-to-date. The excellent original illustrations have been retained and added to so that the book still stands out as a compact well arranged treatise on pediatrics. It is remarkable how well the authors have covered the vast field of medicine in a condensed well written and easily read volume of which the text is simple enough for the medical student and general practitioner and still technical enough for the pediatrician or special student in children's diseases. The tendency in the recent past has been to elaborate and enlarge text books on pediatrics or to get away from the single volume work and it really is pleasing to find at least one of the established books retaining its character of condensation and simplicity.

WM. HENRY DONNELLY.

SURGICAL CLINICS OF NORTH AMERICA. Published every other month by the W. B. Saunders Co. Phila. and London. Per Clinic Year (6 issues), Cloth, \$16.00. Paper, \$12.00. Volume 5, Number 1, February, 1925 (New York Number).

There is sufficient clinical material in this number to keep one busy for a number of weeks reading and digesting it. Of special interest are the clinics of Dr. Pool on gonorrhea, of Dr. Berg on gastric-duodenal ulcer, of Dr. Coley on sarcoma of long bones, or Dr. Moorhead on traumatic surgery. There is a host of others no less important or instructive.

HERMAN SHANN.

Volume 5 No. 2 April 1925 (New York Number)
Volume 5, Number 3, June, 1925 (Mayo Clinic Number)

The issuing of the various volumes of the Surgical Clinics of North America are always looked forward

BOOK REVIEWS

A SYNOPSIS OF MEDICINE. By HENRY LETHBRIDGE TIDY, M.A., M.D., B.Ch. (Oxon), F.R.C.P. (Lond), Assistant Physician to St. Thomas' Hospital, Physician to the Royal Northern Hospital, Fourth Edition, Revised and Enlarged. William Wood and Company, New York, 1925. Price, \$6.00.

The senior medical student, the busy physician and the instructor will find this book gives material assistance in reviewing the subject of medicine. Many useful points, perhaps forgotten, will be brought to his attention again, and the review it affords of many rarer medical subjects will amply repay one for the time not usually devoted to such topics. As a stimulus and guide post for the necessity of further study of a given disease, the book too has a definite use. The general and individual arrangement of subjects is excellent and the field of medical diseases is clearly but not too briefly summarized. Occasionally an omission of value is noted as carbon monoxide poisoning and the estimation of basal metabolism in hyperthyroidism. Where by necessity such a vast subject must be confined to a small volume the sections devoted to treatment always appear to be less satisfactory than the others. Of the many books "providing a synopsis" of medicine this will be found most complete and properly employed, of value to every physician.

HENRY WOLFER.

IMMUNOCHEMICAL STUDIES Edited by CARL H. BROWNING, Gardiner Professor of Bacteriology in the University, and Director of the Laboratory of Clinical Pathology, Western Infirmary, Glasgow. Contributors: C. H. BROWNING, Glasgow; M. KOSAKAI, Japan; T. J. MACKIE, Edinburgh; T. TANIGUCHI, Japan; G. H. WILSON, Birmingham; and N. YOSHINARE, Japan. William Wood & Company, New York, 1925. Price, \$4.50.

This volume of 230 pages discusses detailed investigations by six contributors upon humoral aspects of immunity. The contents are made up of 8 chapters.

1. Introductory. On Antibody Action in General. By C. H. Browning.

2. Properties of Antigens as Exemplified by Globin and Haemoglobin. By C. H. Browning and G. Haswell Wilson.

3. Mature and Immature Antibodies—Alterations in Haemolytic Immune Body which occur during the Process of Immunization. By C. H. Browning and G. Haswell Wilson.

4. Constituents of Serum which influence Antibody Action—The Natural Haemolysis of Ox Serum from Guinea Pig Blood and Conglutination. By N. Yoshinare.

5. The Effect of Osmic Acid and other agents on the Affinity or Receptors for Immune Bodies and on their Antigenic Properties. By M. Kosakai.

6. Heterophile Antigen and Antibody. By T. Taniguchi.

7. Opsonic Action. By C. H. Browning.

8. Complement. By C. H. Browning and T. J. Mackie.

These detailed contributions on the complex agents which enter into our immune reactions offer interesting reading to the medical worker who has an interest in laboratory technique or in mathematics.

H. M. FEINBLATT.

ON WRITING THESES FOR M.B. AND M.D. DEGREES. By Sir HUMPHREY ROLLESTON Bart., K.C.B. 16mo of 28 pages. London: John Bale, Sons & Danielson, Ltd., 1925. Paper, 1 shilling.

A thesis is a conglomeration of words that ought never be written, if written, it ought never be published, if published, it ought never be read. The underlying principle of the thesis is correctly explained in this pamphlet. The candidate for the degree picks an intellectual fight with the Dean, and the contestants strike verbal blows indiscriminately both above and below the scientific belt. If medical literature is to be not an accurate report of careful observation and unbiased judgment, but nothing more than an intellectual bout, let us hope for another Alexandrian conflagration.

The above outburst is aimed not at the pamphlet reviewed but at the sinful practice of writing theses. The pamphlet itself is interesting reading, it is also instructive. If the candidate is compelled by custom to write a thesis in classical style, he must fall in line or do without the degree. This pamphlet contains a number of valuable pointers, a knowledge of which will give the candidate an even break with the Dean.

FREDERICK DAMRAU.

SUBMUCOUS ENDOCAPSULAR TONSIL ENUCLEATIONS. With discussion of the evolution of knowledge of the tonsil as a disease producing factor and various methods of enucleation. Excerpts from Clinics of Charles Conrad Miller, M.D. The Oak Press, Chicago, 1925.

This is a book of two hundred and eighteen pages which the author chooses to call a monograph on the subject of "Submucous Endocapsular Tonsil Enucleation." The first two pages, some of the illustrations, and only a comparatively few of the following pages are devoted to the elucidation of the subject of the author's treatise.

The remainder of the text is a very interesting and instructive exposition of the subject of the tonsil, its diseases, complications and surgery. There is also enlightening information on the bacteriology and structure.

The almost complete reprint of Wessely's article on "Meningeal Infections Following Peritonitis" is one of the features of the book.

The author has strayed far from the subject matter of his original intention, with the result that his book bears all the earmarks of a good textbook on the subject of the tonsil and certain of its phases.

The title is misleading and does not do justice to the contents of the book. The addition of an index and a bibliography would enhance its value and make it a deserved addition to the textbooks on the subject of the tonsil.

HEALTH THROUGH PREVENTION AND CONTROL OF DISEASES. By THOMAS D. WOOD, M.D., College Physician and Adviser in Health Education Teachers College, Columbia University and HUGO GRANT ROWELL, M.D., Physician Horace Mann Schools, Teachers College, Columbia University. World Book Company, Chicago, Ill., 1925.

The all-including and pretentious title of this booklet is rather misleading inasmuch as the authors simply present a brief review of the role of teachers and nurses in the problem of freeing the school from becoming the hot-bed for the spread of infectious diseases among pupils.

The discussion of the important role of the medical school inspector is entirely omitted. The booklet gives and quotes the practices of various cities with respect to lay inspection of school children their exclusion readmission, etc. It also gives instructions how to recognize the onset of various school child infections. It does not state how the teachers should be trained and

ASTHMA AND THE CALCIUM ION*

HAROLD A. PATTERSON, M.D., F.A.C.P.

SONYEA N Y

THE subject of asthma has been approached from various angles. Early opinion considered it as a pure neurosis. Some have attributed it to errors in diet without regard to any definite opinion as to the nature of such errors. Others have attributed it to reflex origin, with the reflex arising in the nose, sinuses, gastrointestinal canal or in fact, in any organ or tissue of the body whose afferent nerves are able to mediate with the pulmonary branches of the vagus. The most recent suggestion is that of anaphylaxis. This idea of sensitization, however, must not be interpreted too narrowly, since with our present knowledge of the subject, hypersensitivity can not be considered as the only factor active in the productions of paroxysms. Asthma is not as simple as that. Indeed, the subject must be approached from a very broad viewpoint. The underlying reacting capacity of the individual's bronchial neuromuscular mechanism must be taken into consideration as well as the exciting cause.

Inheritance is regarded by many as a factor of considerable importance in sensitization. It is also a matter of common knowledge that many hypersensitive individuals are asthmatic. In fact, Wells is authority for the statement that fatal anaphylaxis is practically limited to asthmatics. All these facts seem strongly to indicate that there is something in the make-up of the asthmatic patient which makes him susceptible to the action of proteins, reflex stimulation, climatic change and physical and chemical irritants.

Asthma has long been looked upon as a disease without an anatomical basis, largely because of the fact that it has been considered as a neurosis, which as such would naturally be regarded as having no pathological anatomical changes. Recent and painstaking investigation, however, would seem to indicate that asthma has apparently an essential pathology which consists in a

thickening of the entire bronchial wall that at times almost obliterates the lumen of the tubes. Thickened musculature and enlarged mucous glands probably afford an instance of anatomical changes resulting from an over-stimulation of a physiological process for in asthma the vagus nerve, which stimulates both the musculature and the secretory glands of the bronchi, is in a state of hyper-irritability. Consequently, these tissues are subject to prolonged vagus action.

A discussion of asthma, therefore, should include not only the exciting agents but also those factors which are accountable for the paroxysms. Consequently, the following subjects require careful consideration.

1 Such stimulating factors as are associated with climatic change or physical and chemical irritants.

2 Inflammations and other irritations which cause reflexes to express themselves in the pulmonary branches of the vagus, such as those arising in the nose, sinuses, gastro-intestinal tract, genital system and even the lung itself.

3 Substances to which the patient becomes sensitized—such as pollen, food, animal emanations, etc.

4 The susceptibility of the patient to react to causative agents. Under this heading comes—

(a) Hyper-irritability of the bronchial division of the vagus nerve, usually with a general vagotonia as well, (b) A relative increase in the potassium as compared with the calcium ions in the cells of the bronchi, (c) Changes in those incretions which disturb the balance in either the nerve mechanism or the ion content of the cell and probably the colloidal phases of the cell itself, particularly the thyroid, the pituitary and the parathyroids.

The first two of these constitutes factors whose potency has long been recognized and with which you are all doubtless familiar. It is with the two latter sets of causes, particularly with the last, that this paper is especially concerned.

The relationship of asthma to the visceral

* Presidential Address 1925 read before the Livingston County Medical Society at its Annual Meeting at Geneseo New York, on October 13 1925

to not only by the surgeon, but by the general practitioner as well, for they give, in the most concise and reasonable way, the best summary of the recent work in surgery and diagnosis.

The procedure employed by the outstanding surgeons of the country is made possible to a large group of surgeons and practitioners by these volumes.

The April volume of this year's clinics contains an excellent clinic by Dr Charles Gordon Heyd of Post Graduate Hospital, on "Hyperthyroidism, and Its Diagnosis and Surgical Treatment." Dr Pool and Dr Erdmann both have very good clinics on the gall bladder and the bile ducts, giving an excellent summary of the present day accepted surgical treatment for acute conditions involving these organs.

In the June issue, from the Mayo clinic, Dr Judd has an excellent clinic upon diseases of the biliary tract, but the outstanding clinics in this issue are those of Dr Charles Mayo, and Dr Balfour on the stomach, and duodenum.

The interest in the last mentioned clinics is greatly stimulated by the very interesting report of Dr Mann upon experimentally produced peptic ulcers. These volumes should be read by all general practitioners and surgeons.

HERBERT T WIKLE

Volume 5, Number 4, August, 1925 (Chicago Number) Volume 5, Number 5, October, 1925 (St Louis Number) Volume 5, Number 6, December, 1925 (Philadelphia Number)

Whether contributed by the surgeons of Chicago, Philadelphia or St Louis, the quality is the same, the best there is in surgery. It is American surgery of the highest order. The wealth of material presented, the brilliant discussions, and the logical conclusions as to treatment make fascinating reading as well as instructive and enlightening. One does not have, nowadays, to travel hundreds or thousands of miles to see the master surgeons operate, for with a little power of imagination one can visualize almost every step of the operative technique so beautifully and profusely illustrated in the Clinics.

HERMAN SHANN

SCOLIOSIS-ROTARY LATERAL CURVATURE OF THE SPINE

By SAMUEL KLEINBERG, MD, FACS, Assistant Surgeon, New York Hospital for Ruptured and Crippled, Chief of Orthopedic Service, Israel Zion Hospital of Brooklyn. Paul B Hoeber, Inc., New York, 1926. Price, \$6.00.

For years, orthopedic surgeons have tried to wrest from nature the secret of the mechanics of rotary lateral curvature of the spine in the hope of evolving a rational treatment which could be depended upon to correct the deformity or prevent it. An assignable etiologic factor is found in but fifteen or twenty per cent of all cases and for that reason, few have had sufficient enthusiasm to write a volume on the subject.

Kleinberg's interest in the problem extends over a period of years, and his opinions are based in the main on abundant material from the New York Hospital for Ruptured and Crippled. His exposition of the subject contains no radical departures from accepted present-day measures. Refinements of management are dealt with comprehensively, and the relative merit of different modalities are soundly evaluated.

The first five chapters are a bit uninteresting, intimate anatomy, physiology and pathology usually are—but they are essential to a clear understanding of the gymnastic, mechanical and operative phases of treatment which fill the nine later chapters. The essential message contained between the covers may be summed up as follows:

Prophylaxis is based upon periodic health examinations, finite attention ought to be paid to the correc-

tion of minor postural errors not because they are the forerunner of true scoliosis but due to the fact that he has noted improved health follows their correction and feels that they are frequently overlooked in routine physical surveys—such as are given to school children. or mild types of rigid scoliosis, gymnastic exercises, passive stretching with or without corrective braces or corsets are approved of.

The majority of rigid scoliotics need forcible correction by plaster jackets. Various methods are discussed—greatest enthusiasm being expressed for the suspension frame with the spine in hyperextension—or better still, complete recumbency for eight weeks on a convex frame with considerable traction on both head and feet.

Operative fixation to maintain the improved position acquired by the frame is advised in selected cases, after the curve is reduced to a minimum. The author's operation is essentially a spine fusion, a combination of the methods of Hibbs, Albee and Forbes' technique, with the addition of a beef bone splint which Kleinberg feels, adds firmer internal fixation.

This is, of necessity, a technical treatise—well done, worth-while, and a splendid reference book for any medical library.

D E. McKENNA.

LECTURES ON NUTRITION. A Series of Lectures given at the Mayo Foundation and the University of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis), 1924-1925. 12mo. of 243 pages, illustrated. Philadelphia and London, W B Saunders Company, 1925. Cloth, \$2.50.

If this book is released for the general public, it is feared they will not understand its contents, as most of the lectures are beyond their intellectual depths and interests. It contains six lectures, which are largely the republication of data that have been published elsewhere. The subjects considered are Basal Metabolism, the Proportions in which Protein, Fat, and Carbohydrate are Metabolized in Disease, Muscular Activity and Carbohydrate Metabolism, our present knowledge of Vitamins, and relation between Fertility and Nutrition. Physicians and chemists who have not kept up on these subjects will find the book of value.

J ARTHUR BUCHANAN

OUR PRESENT KNOWLEDGE OF HEREDITY. A Series of Lectures given at the Mayo Foundation and the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis), 1923-1924. 12mo. of 250 pages, illustrated. Philadelphia and London, W B Saunders Company, 1925. Cloth, \$2.50.

Castle opens the book with a lecture on "Heredity The General Problem and Historical Setting." He does not define heredity, nor does he state what "The General Problem" is. The historical setting of heredity, a fascinating part of the development of biology, is so briefly considered in this lecture that it contains but little of its interesting features. Practically none of the terms used in this lecture are defined, and unless the reader is a biologist or a physician, the chances are that he will fail to appreciate the lecture. The last two paragraphs of the lecture are important. They speak a spirit of conservatism which is disregarded by those who follow Castle in the book.

McClung lectures on "The Heredity of Sex," Delfsen on "The Inheritance of Acquired Characters" and Wells on "The Influence of Heredity on the Occurrence of Cancer" and Maud Slye on "Heredity in Relation to Cancer." Most of the data presented has appeared elsewhere and in more detail. Guyer closes the book by a lecture on "Eugenics." A good deal of the data on which he bases his arguments have been discarded by psychologists.

J ARTHUR BUCHANAN

The altered nerve and cell reactivity of the asthmatic individual is interesting. It would really seem that asthmatics belong to a particular group of individuals possessing a vegetative nervous system in which parasympathetic activity prevails. Now in order that such a status may exist, certain conditions must obtain in the body cells themselves. In other words, increased parasympathetic action (vagus in asthma) presupposes a relative increase in potassium as compared with calcium ions in the cells—i. e., either an actual decrease in the calcium or an absolute increase in the potassium. It is quite probable that this state of relatively increased parasympathetic potassium activity in the cells may be partly inherited and partly acquired.

Possibly at this point it may be interesting to speculate just where the reaction takes place in asthma. As has already been indicated, it would seem in many cases that there is a close relationship between the asthmatic and the anaphylactic reaction. In fact, in those cases where the asthmatic manifestations are apparently due to the influence of foreign protein, sensitization seems identical. Moreover, the weight of evidence seems to favor the view that the principle state of activity in anaphylaxis is in the cells themselves. Hypersensitive cells during the reactive stage show change in their colloid phases which can be removed by desensitization. That this change in the colloidal arrangement of the cells is responsible for the shifting of the ion equilibrium may be conjectured. At any rate, that the change is evidenced by lessened sympathetic action which is associated with a relative deficit in the calcium ions and an increased permeability of the cell membrane and an associated hyperactivity on the part of the parasympathetic nerve is definite. Further speculation in this realm, however, would lead us too far afield and hardly lies within the scope of this paper.

Since many asthmatics also suffer from other manifestations of protein hypersensitizations, it is important to consider whether there is not some defect in their neuromuscular mechanism—either a decrease of sympathetic irritability or a decrease in the calcium ions of the cell on the one hand, or a hyperirritability on the part of the parasympathetics, or an increase in the potassium ions in the cell on the other hand—which antedates and underlies an asthmatic syndrome. It is quite easy to understand how these individuals who manifest hyperirritability on the part of the neurocellular mechanism of the bronchi would respond with an asthma whenever this system is unduly stimulated, either reflexly or by such a condition as protein sensitization or by changes in weather and climate or mechanical or chemical irritants. Furthermore, in considering the causation of this underlying condition, one must bear in mind the fact that certain glands of internal secretion stand in an important relationship

to calcium metabolism and the activity of the sympathetic and the parasympathetic systems. In other words, asthma can be regarded from this viewpoint, as a condition in which the bronchial neurocellular mechanism reacts profoundly to stimuli that do not effect, apparently, normal individuals, that is, a local vagotonia, according to Eppinger and Hess. But in this sense, vagotonia which has hitherto been regarded as a hypersensitive condition of the parasympathetic nerves, must be given the broader definition of Pottenger. It thus becomes a condition not of nerves alone but of the cells acted upon as well. A condition in which the ion content of the cell is disturbed, the permeability of the cell membrane increased and the potassium-calcium equilibrium disturbed by a relative overbalance in favor of potassium so that a reaction on the part of the cells at least when stimulated by the parasympathetic nerves results in a reaction which is beyond the bounds of physiological activity. Such a reaction could, of course, be precipitated in two ways, either by direct action upon the cells or by stimulation of the bronchial fibers of the vagus nerve.

Applying the principle of the action of the neuro-muscular mechanism to asthma, the possibility of relaxing the bronchial spasm and relieving the bronchial secretion by changing the electrolytic content of the cells suggests itself as a therapeutic possibility. The literature contains an account of cases in which this has been done. In these cases an attempt was made to introduce sufficient calcium to restore the normal neurocellular equilibrium of the bronchial tissues, in as much as an increase in the relative amount of calcium in the cell causes the same physiological action as stimulation of the sympathetic system.

The treatment described is as follows. The patients under trial were kept in bed continuously. Treatment was begun with small amounts—5 c.c. of a 5 per cent solution of calcium chloride intravenously—and increased to double the initial amount if necessary. The injection was repeated every few days and the effect carefully observed. It was found best to inject the solution slowly, taking from four to five minutes for 10 c.c. in order to avoid mild untoward effects. At this rate of injection a slight facial flush was noted and the patient was conscious of a feeling of warmth, most pronounced in the face and in and over the abdomen. The blood pressure rose from 5 to 10 points following the injection but usually returned to normal within thirty minutes. The pulse rate in asthmatics sometimes dropped from 10 to 20 points per minute but persisted at the lower rate for only a short period. With more rapid injection the patient became decidedly uncomfortable, complaining of a sensation of intense heat in the skin with profuse perspiration, a sense of constriction

nerves is rather complex. For convenience, the various syndromes manifesting themselves during the course of visceral diseases may be classified according to the manner in which they effect the two components of the vegetative nervous system. The symptoms accompanying these diseases fall either into the group of sympathetic syndromes or into that of parasympathetic syndromes, depending upon whether the irritability of one or the other system predominates. Thus, in asthma, the spasm of the bronchial musculature and the increased secretion which is evident during the paroxysm, constitutes the asthmatic syndrome. The rapidity of heart action and the increased respiratory effort during asthma may be looked upon as incidental symptoms and not as an integral part of the syndrome. In this condition, there is an increase in the tonus of that portion of the sympathetic which supplies the bronchial musculature and mucous membrane. Its causes may be as diverse as the irritants that can be applied either to the nerve centers giving origin to the pulmonary fibers or to the peripheral nerves that are in reflex relationship with them.

It is a well known fact that in the bronchi, the vagus of the parasympathetic system and the sympathetic are antagonistic in action. Thus stimulation of the vagus causes contraction or spasm of the bronchial musculature and an increase in bronchial secretion, while stimulation of the sympathetics, on the other hand, relaxes the bronchial musculature and decreases bronchial secretion.

This antagonistic relationship of these two components of the vegetative system is definite, as may be inferred from the fact that the commonly successful method of relieving the paroxysms of asthma consists either in using remedies which will inhibit the action of the vagus or those which will cause a relative increase in the antagonistic sympathetic action. Atropine is a drug which produces the former result, but since it can not be given in full inhibiting doses without causing great discomfort to the patient, its use is of limited value. Adrenalin has been the most successful individual remedy heretofore employed to combat the paroxysm. It effects this result by producing the same action upon the bronchial musculature as though the sympathetic nerves were stimulated and so tends to restore the normal sympathetic, parasympathetic balance. Unfortunately, however, its usefulness is greatly limited by the fact that its action is transitory. It will relax the spasm and afford relief within a few minutes after it is injected, but the duration of its effect is but a few hours after which the injection must be repeated. The effect in this instance is due to stimulating the sympathetic mechanism sufficiently to inhibit the vague and relax the spasm. This action may effect both the nerves and the ions in the peripheral cells.

A consideration, therefore, of the relationship

between the ion content of the cell to the vegetative nerves is in order. Authority is not lacking for the statement that action in the neuromuscular apparatus depends to a great extent upon the condition of the body cells. Furthermore, the condition of the body cells determines to a very remarkable extent their own action and likewise the manner in which they will react to nervous and chemical stimuli. Under differing conditions the cell may differ physically, that is to say, in the physical character of the colloids which compose it, or in its electrolytic content and each change alters its reactivity. Among other electrolytes the body cells contain calcium, potassium and sodium in certain relative proportions. A variation in the relative amount of these different ions contained in the cell may alter its function in the same manner as though its nerve equilibrium were disturbed. Indeed the ion content is an essential part of the neuromuscular mechanism.

A considerable wealth of pharmacological observations—some of which, such as the classical studies of Ringer in 1881 to 1883, were made long before sympathetic and parasympathetic action was understood—indicates that the cellular electrolytes can be divided into sympathetic and parasympathetic groups, after the fashion by which certain drugs, much as adrenalin, atropine and pilocarpine are classified. This possible division of cellular electrolytic content emphasizes the intimate relationship between the innervation and the ion content of the cell as it is understood from the viewpoint of vegetative neurology. In fact, experimental evidence indicates quite definitely that stimulation of sympathetic and parasympathetic systems produces different effects upon the cells of an organ and may even cause these cells to give out into the blood stream certain definite substances which vary according to which system of nerves is stimulated. With the newer conception of physiology, bio-chemistry and bio-physics, one may assume that nerve stimulation results in changing the cell so as to cause it to take from or give out certain substances into the blood stream. It is quite probable that this effect is partially caused by producing changes in the colloids of the cells. There is no doubt that action in body cells is associated with changes in the permeability of the cell membrane and the binding more firmly or the giving off of various ions. In this connection the work of a number of observers is considered to have established the interdependence of the sympathetic nerves and the calcium ions in the cell. This conception is of fundamental importance for the understanding of the action of the neurocellular mechanism and not only suggests the manner in which certain diseases may produce their effects upon the organism but also further affords certain definite principles of rational therapeutic attack.

THE INEFFICACY OF INTRAVENOUS CALCIUM INJECTIONS IN ASTHMA, HAY FEVER, AND ALLIED CONDITIONS

By AUGUST A. THOMMEN, M.D.

NEW YORK

FEW conditions demand as much therapeutic resourcefulness as chronic asthma. Among chronic ailments, asthma with its complications doubtless causes the greatest degree of suffering over the longest period of years. When, therefore, a therapeutic measure is offered as a cure, or even only as another method of obtaining relief, it is bound to create a considerable degree of interest and enthusiasm. This enthusiasm, however, must needs be tempered by the wisdom gained from past experiences, in which various other modes of therapy were similarly offered, only to be found wanting upon adequate trial and investigation.

The purpose of this paper is to report the failure, at our hands, of a mode of asthma therapy, viz., intravenous calcium injections which, nevertheless, has been reported upon favorably by others.

Pottenger¹ advocated this method of treatment on the basis that calcium deficiency in the cells of the bronchial trees was responsible for the asthmatic paroxysm. This deficiency, he thinks, is due to either a hyperactivity of the vagus, causing an increased potassium content in the cells, or to a hyperactivity of the sympathetic system which results in a direct decrease in the calcium content. He reported four cases as being entirely relieved, some with as few as three injections.

Besides this neurochemical conception, various other theories have been offered to explain its action. Some have thought that it inhibits the proteolytic processes, or so modifies them as to render the protein split products less toxic, while others have conceived of its acting in such a manner as to lessen nerve-ending irritability. All such attempts at rationalizing empiricism tend merely to emphasize the fact that the real test of any such mode of therapy lies in the results obtained.

In all, nineteen cases of asthma, belonging for the most part to the non-sensitive group, were intensively treated by this method. Two preparations were used: (1) a 5 per cent solution of calcium chloride in doses of 5 to 10 c.c., (2) a proprietary in the form of a 10 per cent solution of calcium urea. Some cases were treated exclusively with one or the other. The majority, however, received injections of both. A total of 198 injections was administered. They were apparently very well borne, for no untoward effects were observed. In several instances the

possibility of a resulting kidney irritation was considered, but not substantiated. The injections were invariably accompanied by a sensation of intense heat, felt most commonly in the chest, the temples, and the rectum, occurring within a few seconds of the beginning of the injection. This evidently disagreeable sensation is very fleeting, and is easily controlled by giving the injection slowly. The caustic, escharotic nature of calcium, evidenced when injected into the subcutaneous tissues, was not observed. It is, however, a possible accident which must ever be kept in mind.

With the exception of two children, aged 11 and 13, the group was composed of adults, seven males and ten females. The duration of illness varied from three years to thirty-two years, with the average about ten years. The injections were administered bi-weekly in most cases, in others, every day. One patient, who was considered a particularly good subject, received injections twice daily for four successive days. The number of treatments given was as follows:

One received 5 injections, four received 8 injections, six received 10 injections, five received 12 injections, two received 13 injections, one received 15 injections.

Results—No marked effects were observed in any case. When used as a succedaneum for adrenalin, to control the paroxysm, it proved entirely valueless. In a few instances an apparent improvement occurred with the first injection. This, however, was always short-lived, and could easily be explained on the basis of the psychological effect produced by a somewhat impressive mode of therapy, or as a natural period of amelioration.

Another means whereby the value of intravenous injections of calcium might be established, perhaps more accurately, is to observe its effects in those allergic conditions in which the various syndromes are more definite and clear-cut, and less apt to be masked by co-existing complications and sequelae. Hay fever, urticaria, angio-neurotic oedema and serum-sickness lend themselves in something of an ideal manner to the study of the efficacy of any particular mode of therapy. Calcium administered intravenously has been recommended for these conditions in the same positive manner, and with a show of the same type of enthusiasm, as in the case of asthma. Any estimate, therefore, arrived at in regard to these ailments, might with reason be used as an aid in the interpretation of the results obtained in the treatment of asthma.

Injections of pollen extracts, given prophylac-

in the throat and a feeling of nausea that persisted for upwards of thirty minutes

In the report of a small series of individuals so treated by Pottenger, to whom the writer is much indebted for material used in this paper, improvement is stated to have resulted in each case after the injection of a series of from 5 to 14 doses of calcium chloride. The administration of calcium is said to have relieved both the bronchial spasm and the bronchial secretion as would be expected from the physiological control of these tissues, since both muscular and secreting glands are activated by the vagus nerve and inhibited by the sympathetic with which calcium works in harmony.

Calcium has long been recommended by mouth in the treatment of asthma but apparently without any definite understanding of how it acts or what doses are necessary to produce any particular effect. Since it is now known that calcium forms an integral cellular constituent and is necessary for sympathetic nerve action, one has a basis for its use founded on rational biological principles by increasing sympathetic action in the neuromuscular mechanism of the bronchi. Vagus action is depressed or inhibited and if the action is sufficiently strong the asthmatic paroxysm is relieved. How long its action would last must be determined empirically by experience. The question of dosage is one that will require considerable attention. It is, no doubt, an individual matter depending upon the degree of disparity between the sympathetic and the vagus tonus in the bronchial neurocellular mechanism in each case.

In asthma the action of calcium upon the cells results in the same physiological process as the administration of adrenalin. Adrenalin heretofore has been the most successful remedy in the relief of paroxysms but its disadvantage lies in the short duration of its action. Experience seems to indicate that the action of calcium will be of more prolonged duration and consequently that it may prove more efficient in supplementing the action of adrenalin and relieving the asthmatic paroxysm for a longer time.

A CASE OF SUBACUTE INFECTIVE ENDOCARDITIS WITH MYCOTIC ANEURYSM AND MENINGEAL SYMPTOMS *

By DAVID P WALDMAN, M D, and MORRIS H KAHN, M A., M D

NEW YORK

THE following case of subacute infective endocarditis is of unusual interest because of the presence of mycotic aneurysms, one of which was mistaken for a submaxillary lymphoid gland, and the presence of meningeal symptoms.

Case Report—H G, aged 20, gave a history of occasional tonsillitis, and at the age of 14, aching pains in her joints but without fever. Her present illness began two months before she came under our observation with pains in the joints and slight fever. For two weeks she had sore throat and soon developed a swelling on the left side of the neck below the angle of the jaw. She had fever, became pale and for one week complained of pains across the abdomen and in the loins.

Physical examination showed slight pallor and apparent loss of weight. The tonsils were enlarged and adherent to the pillars of the fauces. There was a group of petechiæ with white centers over the right chest and neck. In the middle of the right palm and instep there were two fading subcutaneous nodules. There were no petechiæ in the conjunctivæ.

The heart was enlarged with a suggestion of a systolic thrill at the apex. There was a systolic musical "canary bird" murmur over the apex, axilla, and precordium and a blowing systolic murmur over the precordium. There was also a faint diastolic murmur over the sternum. The pulse was small.

Below the left angle of the jaw there was a swelling the size of a walnut which was not moveable, not adherent to the skin, but which had a distinct arterial expansile pulsation. It gave the impression of an enlarged gland on first examination, but was definitely a mycotic aneurysm of the external carotid artery. The left radial pulse was smaller than the right. The femoral vessels were negative.

The lungs were clear. There was slight tenderness on pressure in the loins and over the spleen, but the latter was not enlarged. The extremities were negative.

A diagnosis of subacute infective endocarditis was therefore made.

On February 23, 1925, five days after this examination, the petechiæ were more numerous, scattered over the neck, chest and abdomen. A new subcutaneous painful nodule developed on the left thumb.

It was decided to try intravenous injection of the various anilin dyes that have been reported effective as bacteriostatic agents. On February

25, an intravenous injection of 10 c.c. of a 0.5 per cent solution of neutral acriflavine was given and on February 26, 15 c.c. of the acriflavine solution was given. There immediately was a sensation of burning of the eyelids and lacrimation, tingling of the lips, weakness, pallor of the face, flushing and a fleeting blotchy erythema. During the second injection, the patient vomited.

On February 28, it was found that the patient had slight rigidity of the neck and a slightly positive Kernig sign. This was interpreted as meningeal irritation, which symptom is found present in a considerable number of cases of subacute infective endocarditis.

The temperature ranged between 101.6 and 103.

A sister of the patient whose blood was found satisfactory as donor by hemolysis and agglutination tests was given injections of a stock vaccine streptococcus viridans. On May 1, transfusion of 250 c.c. of blood was made taken from this donor and injected into the patient. The blood count immediately before the transfusion was hemoglobin, 68 per cent, red blood cells, 2,464,000, white blood cells, 10,000, polys, 60 per cent, lymphos, 40 per cent. The day following the leucocytes were 15,000 per cmm with 92 per cent polys and 8 per cent lymphos.

Within 24 hours, the temperature rose to 105.4 and gradually fell to 101, continuing between 101 and 103. One week later, the condition of the patient was worse. There was more emaciation and rigidity of the neck. Numerous small and large petechiæ were scattered over the neck, chest and extremities. Intravenous injection of 40 c.c. of a 0.4 per cent solution of gentian violet was given. Two days later the patient gradually lapsed into coma with increasing rigidity of the neck, and finally died. Unfortunately, permission for autopsy was not granted.

The interest in this case centers especially around the occurrence of a mycotic aneurysm of the left external carotid artery, located below the angle of the jaw. This mass was assumed to be an enlarged lymphoid gland until the diagnosis was made by Dr. Morris H. Kahn who was consulted in the case and directed the subsequent treatment.

Clinically, mycotic or bacterial aneurysms are of interest as they involve the peripheral arteries. Bacterial infection of the vessel wall is the most common cause of aneurysm and in most cases it is associated with some form of bacterial endocarditis.

In the larger arteries, septic emboli may lodge

tically, represent the most efficacious method for the treatment of hay fever. When given phylactically, the results are less certain and rarely as beneficial. Furthermore, because of the rule of specificity which obtains in this method of treatment, the extracts must be prepared from the particular pollens to which an individual is found sensitive, or represent several important members of a large botanical group, in which each species may be a positive exciting cause. There are cases of true hay fever in which the particular offending pollens are most difficult to ascertain, and some there are which have proven quite insolvable. It is readily apparent, therefore, that a method of treatment which would prove helpful in undiagnosed cases of hay fever, and which would also act as an effective adjuvant to pollen injections when given phylactically, is a decided desideratum. The intravenous injection of calcium has been advanced as just such a method. One is led to believe by the reports published, particularly by several German writers, especially Schliack² and K. Eichwald³ and in a leaflet which formerly accompanied the proprietary, that one intravenous injection of calcium would suffice to prevent the onset of hay fever, or to control the symptoms if they had already developed. It was intimated that three, or possibly four injections, administered several days apart, might have to be given in especially recalcitrant cases.

In this study of hay fever, both Afenil and plain calcium-chloride were also used. The cases grouped themselves as follows:

- A—Undiagnosed cases, two
- B—Cases seen for the first time after the onset of symptoms, fifteen
- C—Cases treated prophylactically, but which developed moderately severe symptoms, fifteen

In each instance an endeavor was made to give this mode of treatment an adequate opportunity to demonstrate its effectiveness. Hence, the number of injections was always in excess of that recommended.

In group A, the two cases belonged to the early type, with seasons respectively from about May 15 to June 6, and April 20 to May 10. From their histories of recurrent attacks, the former for thirty-eight years, i. e., since the age of four, the latter for ten years, and their symptoms, they are undoubtedly cases of hay fever, yet both gave negative skin and eye tests to the grasses and to a goodly number of tree pollens, except a strong extract of Scarlet Oak, i. e., 05 mg. of nitrogen per 1 c.c.

They received treatment with scarlet oak empirically, and nine injections each of calcium intravenously, three of which were given within the week just preceding the onset. It was very evident that neither the pollen extract nor the calcium had any effect on the onset, duration, or intensity of the symptoms.

In group B, fifteen cases were treated phylactically with appropriate pollen extracts, and a total of 60 calcium injections.

Six patients received 3 injections, six patients received 4 injections, three patients received 6 injections.

Results—They must be reported as negative, for there was no apparent difference from similar cases treated only phylactically.

In group C, an attempt was made to use calcium in an endeavor to bolster up the results obtained in previous years with pollen extracts in a selected number of cases.

Five patients received 3 injections, six patients received 4 injections, three patients received 6 injections.

Results—Here, too, the results were negative, apparent benefits being easily explained by natural variations in the intensity of symptoms.

Four cases of urticaria, two of angio-neurotic oedema, and one of serum-sickness were treated by means of calcium injections. In none of these cases was there any benefit, definite and readily apparent.

Conclusion—In view of these facts, one is constrained to record the conclusion that intravenous calcium therapy is of doubtful value in asthma, hay fever, and cognate conditions.

conditions and it can be induced or made to return towards normal almost at will. It is not necessarily an indication for the use of diet but it does reflect a change in the blood supply and consequently in the physiology of the muscular tissues at least.

The premise from which the use of diet in arthritis originally arose was the observation that after severe operative procedures certain arthritics experienced an astounding benefit coincident with the incidental period of fasting which usually followed. Further studies showed that this fast was not the only factor involved and that stimuli of various kinds affecting the sympathetic system, such as excitement and great anxiety, the use of non-specific protein, as well as agents which tend to hasten metabolism, may also have a favorable influence upon the rheumatoid syndrome in certain cases. In order to explain on the one hand, the unfavorable action of focal infection at a distance, the effect of exposure, fatigue, over-eating, the menopause, the nature of Charcot's joint and the high incidence of arthritis in mid-life, and, on the other hand, to explain the action of factors making for convalescence, such as heat, massage, exercise, a reduced diet, pregnancy and metabolic stimuli like radium and arsenic it is necessary to admit a disturbance of underlying physiology expressing itself widely throughout the economy and subject to many influences.

It is clear, today, that the local metabolism is undoubtedly caught up in the problem of arthritis as stated by Nicholls and Richardson in their exhaustive monograph on morphology, and those processes which influence anabolism and especially those which hasten katabolism may be of great significance. The viewpoint that the physiology as a whole and the local metabolism in particular are concerned in the pathology of arthritis is of the highest importance. It explains the futility of depending upon any one measure in the treatment of this disease and also the importance of correlating various influences and modes of treatment. Even if one should grant that all cases of arthritis are due to local bacterial infection alone, the conception that bacteria are the agents which bodily remove bony tissue and bodily deposit it in the form of overgrowth is almost too primitive to be entertained. In both the physiology and pathology of bone it is fully accepted that chemical processes are at work and the changes in bony tissue characteristic of arthritis can be conceived in their entirety only with the aid of established chemical principles.

A consideration of the arthritic syndrome from the standpoint of physiology and bio-chemistry has thus led to a concept of this disease wider than that which regards it as a local bacterial invasion only. The use of a diet, massage, heat and many other measures can be understood and

applied with greatest success only when this wide angled vision is maintained.

The conception that the intestinal tract plays a rôle in arthritis finds wider acceptance today than it did ten years ago. One evidence of this is the multiplicity of establishments devoted to colonic irrigation and similar treatments (facetiously called colon filling stations). The application of these measures to a definite proportion of arthritics cannot be successfully denied. It must follow that these treatments partake something of the nature of the Augean stable, however, unless consideration be also given to that which is taken into the intestinal tract, namely, the food. It is precisely the nature of the food intake which determines that which is removed by irrigation. The use of diet, however, is very much more fundamental than measures which merely stimulate or evacuate the colon or ileum and operates quite independently of them.

Following the accepted viewpoint that most cases of arthritis are due to the propagation of bacteria in one or more localities, it is entirely conceivable that part of the influence of diet in appropriate cases may depend upon a reduction of the bacterial substrate. As a result of this fewer bacteria and bacterial products are presumably produced within the intestinal canal. This cannot be accepted, however, as the only explanation since in most cases the amounts of food normally present are very large and the small reduction of food sometimes adequate to achieve benefit is too slight relatively to be regarded as having large influence on the effective total substrate. If the matter were merely one of keeping the intestinal canal swept out and purged of bacterial products one should obtain larger results from purgative measures and from the use of acidophilus organisms, neither of which bears any constant relation to improvement. In fact, in some cases, on a reduced diet, convalescence has continued in the presence of constipation of four days standing and a marked rise in the æthereal sulphates as indices of so-called putrefactive processes. Furthermore, in border line cases the ingestion of large amounts of food may be followed within a short period of an hour or two by an increase of symptoms such as stiffness. The time thus involved is probably too short to permit of commensurate bacterial activity. It is common knowledge that even in health a great intake of food may induce hebetude and lethargy, probably through an influence on the blood flow, and there is reason to believe that it is through an influence on the blood flow that a curtailment of diet finds part of its effect in arthritis.

Experiments demonstrating circulatory changes in the muscles, elsewhere reported in part(1), suggest strongly that the normal physiology of these tissues is disturbed. The ordinary process of removal and utilization of at least one blood

in the vasa vasorum and produce a point of suppuration, later the overlying intima ruptures and in this way an aneurysm may be formed.

Stengel and Wolferth reported a number of cases of mycotic aneurysm of intravascular origin.¹ From the literature on the subject, they concluded that mycotic aneurysms arise in one of the following three ways:

1. From infected emboli in the lumina of vessels or in the vasa vasorum. Richey and MacLachlan have reported two cases in which both aneurysms had their beginning in the bacteria laden emboli which were swept off the affected heart valves, lodging in the bifurcation of the arteries involved.²

2. The settling of bacteria on the inner surface of a vessel or in the vasa vasorum.

3. Continuity or contiguity of infection from the aortic or pulmonic valves.

In our case, the early development of the aneurysm in the left external carotid artery suggests its origin to be purely embolic. At the time we first observed the case on February 17, 1925, the heart signs were considerable and there was tenderness over the spleen and in the loins, suggesting the possibility of multiple emboli having occurred.

¹ Stengel and Wolferth *Arch Int Med* 1923, Vol XXVI, p 527.

² Richey and MacLachlan *Arch Int Med*, 1922, Vol XXIX, p 131.

As noted in the case report, the left brachial and radial pulses became considerably smaller than the right. This persisted to the end. The explanation to be made of this is the development of a mycotic aneurysm of the left subclavian artery with mural thrombosis producing partial obliteration of the vessel.

The occurrence of symptoms of meningeal irritation is probably more frequent in cases of subacute bacterial endocarditis than is noted in the literature. In this case, the meningeal symptoms were not developed until several weeks before death. They are probably due to petechiae or to embolic effects in the meninges.

The efficacy of intravenous injection of dyes in this case cannot be judged by the results as the condition was much advanced when these measures were instituted.

SUMMARY

A case is reported of subacute bacterial endocarditis presenting an etiology in tonsillitis, joint pains, and the characteristic symptoms of fever, progressive pallor, extensive valvular heart involvement, numerous petechiae, symptoms of emboli in the spleen and kidneys, the development of mycotic aneurysm in the left carotid artery, and finally signs of meningeal irritation. The intravenous use of dyes and transfusion of blood from a donor immunized against streptococcus viridans were of no avail.

THE SIGNIFICANCE AND USE OF DIET IN THE TREATMENT OF CHRONIC ARTHRITIS*

By RALPH PEMBERTON, M.D.

PHILADELPHIA, PA.

I HAVE been asked to speak on the significance and use of diet in the treatment of arthritis. I am happy to do this not only because it gives an opportunity of stressing a form of treatment which, in suitable cases, may afford the only measure of curative value but, more especially, because it gives an opportunity to emphasize the necessity of a wide angled vision of the problem of arthritis. An important result of study of this form of therapy has been to lead to a better understanding of the physiology concerned and the pathology on which the symptoms of the disease depend. Emphasis on any one form of treatment of arthritis might lead to an appearance of indifference to other measures and I want at the outset to state that no single agency in treatment can be allowed, as yet, a wholly dominating role. Diet is only one of many useful tools and I am confining my remarks to it because I have been asked to do so. There will be inadequate time to take up more than a few points of pathology and treat-

ment and nothing in my remarks is to be construed as neglect, or depreciation, of the doctrine of focal infection which constitutes one of the signal advances in modern medicine. It is increasingly recognized, however, that it is necessary to do more than remove foci in the treatment of many cases of arthritis and that other factors operate in both the development of the disease and convalescence from it. In learning the important lesson of the relation of focal infection to arthritis, medical acumen has often been dulled to other weighty considerations.

A series of studies begun upon soldiers during the war has led recently to the viewpoint that the actual pathology of arthritis is dependent, in part at least, upon a disturbance in the local circulation of the region involved and probably other regions also. This conclusion had its origin particularly in the observation that focal infection and chronic arthritis are paralleled to a striking degree by a lowered sugar tolerance. This lowered tolerance is not diabetic in nature, it has been shown to depend upon circulatory

* Read by invitation before the New York County Medical Society, May 24, 1926.

such instances this is the only form of therapy which will avail. Improvement may be manifest, exceptionally, as early as the third day but sometimes the lapse of many months is necessary before convalescence is clear. Some further indication of the propriety of a diet in such cases is often to be found in the gastro intestinal X-ray which may reveal a long, dilated and tortuous colon, especially after rectal injection of the Barium.

Diet constitutes no panacea in the treatment of arthritis, however, and it will fail to influence many apparently suitable cases, just as other measures do. It is of the greatest importance to emphasize that there is no single panacea for this disease. Those who believe otherwise confess thereby their ignorance of the problem as a whole and of the many factors involved. While the proliferative type of arthritis is that which apparently best lends itself to dietetics we have been much interested recently in evidence showing clearly that the degenerative form may also sometimes respond to these measures, though not so frequently apparently. The significance of this observation is that identity of etiology in the two types is clearly implied and if the etiology be the same there is implied a lesser justification for sharp separation into types. While accepting and using the classification of Nichols and Richardson as the best, because the simplest and best founded, I am prepared to believe that the physiologic disturbance productive of chronic arthritis may be in the nature of a common denominator underlying all types and that relatively extraneous factors may condition most of the clinical variations. A hint of the nature of this underlying disturbance is given above.

One phase of this subject which needs emphasis is the fact that the careful use of dietetics may sometimes operate even in the presence of what is apparently causative focal infection. Fletcher also (*Arch Int Med*, 1922, vol 30, p 106) observed this in his two series of fifty and one hundred cases. The wise procedure is of course to remove such infection when possible, but from the academic standpoint it is of great interest to observe that there is such an influence. By the same token, it is important to observe that after foci in the teeth, tonsils or elsewhere have induced an arthritis, the disease may be perpetuated by faulty amounts and distribution of the food stuffs. Cases "hanging fire" some months after removal of infections will occasionally improve rapidly when placed on a restricted diet. On the other hand, a restricted diet alone may be

inadequate to achieve benefit but when used as a basis for other forms of therapy such as hydrotherapy, massage, etc., it may be of lasting value. A great lesson in the treatment of arthritis is that combinations of measures will often succeed where one or two alone will fail, and this more or less independently of what these measures may be.

It is pertinent to call attention here to recent studies (*Arch Int Med*, Jan, 1926, vol 37, pp 92-101) by Dr Cajori,² Miss Crouter and myself in collaboration with Dr Osgood, which show very clearly that the joint fluids are in very close communion with the blood stream. As a result of this, sugar ingested by mouth may reach the joint fluids almost immediately and in such concentration as even to exceed the concentration of glucose in the blood. It is clear that glucose is necessary for the nutrition of the avascular central portion of articular cartilage and evidence is now adduced of its ready availability. It is also clear, however, that glucose and presumably other products of normal digestion may reach the joint fluids in excessive amounts and that the way is open for access to the joint cavity from the intestinal tract of various substances of detrimental nature.

In conclusion, I want to direct attention to the important contributions made by some of the orthopedists to the understanding and treatment of arthritis. It is something of a reproach to us internists that we have not, as a group, already made large use of their viewpoint. Through my collaborator, Dr Robert B Osgood, of Boston, I have learned the importance of considering the arthritic as an architectural problem quite apart from the ordinary idea of orthopedic apparatus and correctives. The influence of postural exercise, adequate diaphragmatic descent, a wide costal angle, rest and many other measures should be considered in connection with nearly all types of treatment and constitutes another justification for the plea with which I began these remarks.

Let me conclude, therefore, with the same plea, from the standpoint of one who has long been an interested observer of this disease, that you bring an unprejudiced mind to the contemplation of the great problem of arthritis and a wide angled vision to the treatment of those suffering from it.

constituent definitely does not take place as soon as usual and it is conceivable that under these circumstances the physiology of the muscle cells does not proceed entirely normally when there is a "load" upon it. Indeed in the presence of evidence pointing to a circulatory change it is hard to see how it could.

In view of these considerations and in view of the undoubted benefit of measures which improve the blood flow and hasten metabolism, such as exercise, massage and external heat, it seems likely that at least part of the influence of a reduced diet results from placing a lessened demand upon the machinery of exogenous metabolism, especially in the muscles.

In general, the propriety of a diet is arrived at partly through the exclusion of other causes of the disease. From what has been said it will appear that the essence of treatment of suitable cases of arthritis by means of a dietary consists in a curtailment of caloric intake below that which has been customary for the individual. Of the three food stuffs, the largest quota in our diet is usually carbohydrate and it is from this source that our calories are most quickly and chiefly obtained. A reduction of caloric intake therefore involves a reduction of carbohydrate although it is generally necessary to curtail protein and fat also. In individuals who are large eaters a reduction of this nature can be easily accomplished without detriment to the nutritional needs. People vary greatly, however, in the amounts they eat, and, in smaller eaters, such a large percentile reduction cannot be achieved. Thus, with the individual ingesting 3,000 calories, a reduction to 2,000 is easy and safe. With a person ingesting 2,300 calories a reduction to 1,800 is practicable but more difficult under average conditions of active life. In subjects eating 2,000 calories or less, further reduction must be made with full consideration of the nutritive and energy problems involved. A fairly useful practical rule in standardizing diet in suitable cases consists in allowing 30 calories per kgm of body weight according to the usually accepted approximate requirements for rest. In fat persons, however, this amount is generally grossly in excess of their needs and will do harm rather than good. No iron clad rule can therefore be given and, if opportunity permits, the best plan is to study, with the aid of a dietitian, the actual caloric intake for a period of about a week under average conditions of life. The dietary habits of the subject can then be closely approximated.

In general, a diet for ambulatory cases amounting to 1,500 to 1,800 calories will derive some 30 per cent of these calories from carbohydrate, 10 or 15 per cent from protein and the balance 40-50 per cent from fat. The nitrogen requirement must be considered from the start, on the basis, of, say, 7 grm or 1 gm

protein per kilo body weight. An abundant supply of "green vegetables" is useful, much as in diabetic therapy, for purposes of satisfying the psychic factors in eating and for stimulation of the digestive juices and peristalsis. In some cases it is necessary to begin with a larger and sharper reduction to perhaps 1,000 or 1,100 calories, shortly increasing this to the point of nutritive equilibrium while keeping the patient confined to bed. In other instances a sharp diabetic fast, or a period of several days on orange juice alone, is necessary.

The chief consideration is therefore first, to reduce the total caloric intake as outlined and second, in diets of relatively high caloric value, to redistribute the food stuffs so that the proportion of calories is larger from fats than in the usual dietary, and less from carbohydrate. This redistribution is of less importance in sharply curtailed diets than in more generous ones, since all three factors are then greatly reduced in any event. There is as yet, however, no precise laboratory guide available, as in diabetes, and reliance must be placed on clinical experience.

Great caution must be urged, however, against the danger of applying these measures to persons already undernourished, anemic or suffering from other complications, such as tuberculosis, infections, etc. There are some exceptions to this generalization and if anemia, joint destruction and pain are being aggravated through the maintenance of a surfeit of food any risks involved must be accepted. Only after the institution of a dietary reduction may cases of this sort cease to grow worse, as has been recently illustrated in the case of a physician's wife now under treatment. The problem then of feeding such cases sufficiently for regeneration of the blood elements, becomes delicate and protracted but can nevertheless generally be carried through successfully when the destructive influences are abated. Cod liver oil is useful at this stage. Lately we have been using in my clinic with considerable success a form of absorbable diet having small residue, the details of which will be published later.

It is difficult to state beforehand the type of case which is appropriate for such dietetic therapy. In general, all operative foci should have been removed, compatibly with good surgical judgment. Dr Russell Cecil, of New York, has recently directed attention again to the important rôle of the climacteric in the production of arthritis among women, regarding these cases as of the metabolic type. It is in this group that the use of diet has some of its widest applications. Well nourished or fat women presenting arthritis particularly of the proliferative type constitute apparently the most promising cases. The success of this form of therapy under these circumstances may sometimes appear magical and, there is no question that in many

such instances this is the only form of therapy which will avail. Improvement may be manifest, exceptionally, as early as the third day but sometimes the lapse of many months is necessary before convalescence is clear. Some further indication of the propriety of a diet in such cases is often to be found in the gastro intestinal X-ray which may reveal a long, dilated and tortuous colon, especially after rectal injection of the Barium.

Diet constitutes no panacea in the treatment of arthritis, however, and it will fail to influence many apparently suitable cases, just as other measures do. It is of the greatest importance to emphasize that there is no single panacea for this disease. Those who believe otherwise confess thereby their ignorance of the problem as a whole and of the many factors involved. While the proliferative type of arthritis is that which apparently best lends itself to dietetics we have been much interested recently in evidence showing clearly that the degenerative form may also sometimes respond to these measures, though not so frequently apparently. The significance of this observation is that identity of etiology in the two types is clearly implied and if the etiology be the same there is implied a lesser justification for sharp separation into types. While accepting and using the classification of Nichols and Richardson as the best, because the simplest and best founded, I am prepared to believe that the physiologic disturbance productive of chronic arthritis may be in the nature of a common denominator underlying all types and that relatively extraneous factors may condition most of the clinical variations. A hint of the nature of this underlying disturbance is given above.

One phase of this subject which needs emphasis is the fact that the careful use of dietetics may sometimes operate even in the presence of what is apparently causative focal infection. Fletcher also (*Arch Int Med*, 1922, vol 30, p. 106) observed this in his two series of fifty and one hundred cases. The wise procedure is of course to remove such infection when possible, but from the academic standpoint it is of great interest to observe that there is such an influence. By the same token, it is important to observe that after foci in the teeth, tonsils or elsewhere have induced an arthritis, the disease may be perpetuated by faulty amounts and distribution of the food stuffs. Cases "hanging fire" some months after removal of infections will occasionally improve rapidly when placed on a restricted diet. On the other hand, a restricted diet alone may be

inadequate to achieve benefit but when used as a basis for other forms of therapy such as hydrotherapy, massage, etc., it may be of lasting value. TRANS-DUODENAL IRRIGATION FOR INTESTINAL CONDITIONS IN MEDICINE, SURGERY, AND THE SPECIALITIES

By M E JUTTE, M D,

NEW YORK

YEARS ago Salisbury¹ asserted that all chronic diseases, except those arising from injuries, infections and poisons, emanated from pathological conditions in the digestive tract brought about by faulty alimentation. No evidence, known to the writer, has been adduced to disprove this claim, on the contrary, much has since become known to support the statement, so that it is not too much to say, that morbid states in some part of the alimentary tract are directly or indirectly the cause of most chronic diseases.

The main factors which bring about unhealthy conditions in the alimentary system are improper food, or improperly prepared food, or foods that are improperly combined, lesser factors are, imperfect mastication, bolting, gorging, lack of fresh air and exercise, drinking not enough water, sedentary habits, nervous strain, emotional disturbances, and advancing age.

The restoration of natural conditions in the digestive system will remove the mainspring of the ultimate disease by doing away with the intermediate pathological states which connect it with the digestive system.

To bring about sound conditions in the alimentary tract, are questions of what in a given case is proper food, of correcting the patient's faulty habits, and of local treatment—this last being the subject of this paper.

Local treatment of the stomach by gastric lavage is well known and extensively practiced, but local treatment of the intestinal tract, by trans-duodenal irrigation, is not yet generally known.

Trans-duodenal irrigation is a treatment which benefits the entire intestinal tract, it flushes all of its sections and reaches any lesion in any of its parts. Trans-duodenal irrigation is harmless, painless and does not weaken the patient, and its results are lasting. It is an aid to nature because it stimulates peristalsis and the abdominal viscera, and because it drains the liver and gallbladder. In doing all this it removes intestinal toxemia and prevents or cures chronic ailments that are the results of toxemia.

Trans-duodenal irrigation is suited to nearly all intestinal ailments and chronic diseases, because by removing the influences that are instrumental in bringing about pathological conditions, it produces conditions in the bowel that approach the normal. The combination of results obtained by the trans-duodenal irrigation makes it a unique regimen required.

treatment. For it accomplishes all three of the objects in view. These objects are to remove the offensive intestinal content, to eliminate or reduce fermentation and putrefaction, and to put the bowel in a health promoting condition generally. The other, older methods of treatment by medicines, purgation, paraffin, attempted antiseptics, colon irrigation, bacterial implantation, and vaccine injections, accomplish, each, not more than one of the objects in view and that one only imperfectly. None is as quick, safe, thorough, and generally as satisfactory as is trans-duodenal irrigation.

Trans-duodenal irrigation was originated by the writer.^{2,3,4} It is an intestinal washout which cleanses the bowel from pylorus to anus. It is given by way of the mouth,⁵ the wash water being introduced into the duodenum through a Jutte duodenal tube, this is done because the solution used is objectionable to the taste and is not tolerated by the stomach, and in order to overcome the control action of the pylorus, which would prevent the passage through it of anything in bulk. The Jutte tube is introduced with a mandrin as far as the stomach, thence it slips almost at once through the pylorus into the duodenum, having only a very small sinker. Then about a quart of a non-absorbable, hypertonic solution, plain or medicated, is run in. Running down the bowel, the solution greatly stimulates peristalsis, so that in less than an hour there are three or four copious, rather watery movements that bring with them all faecal matter, together with what there is of mucus, pus, and toxic material.

The results obtained from trans-duodenal irrigation are prompt and effective removal of all offensive material from both the small and large bowel, drainage of liver and gallbladder, stimulation of peristalsis, re-establishment of normal physiological action in other abdominal viscera, restoration of tonicity of the intestinal musculature. Secondary effects are products of toxic decomposition are kept at the normal, therefore, they do not poison the blood stream and can no longer act as causes of chronic ailments.

Various chronic ailments follow the development of toxemia and of morbid conditions in the alimentary tract. The origin of the trouble may go back to overfeeding during infancy, or it may have been a case of "indigestion" in childhood developing steadily or intermittently into worse troubles in later life, such as diarrhoea, constipation, catarrh, and still later

into stasis and toxemia, to result, it may be, in pernicious anemia, arterio-sclerosis, apoplexy

It is usually not until symptoms of toxemia appear that the patient becomes really worried, because then he begins to feel the depressing effects of the condition. Gradually the vitiated blood affects his general constitution, and the condition becomes a definitely established disease in the part of his body which happens to be the weakest or most abused or most exposed. His attention is called to the organ or part where the trouble has come to a head. He does not appreciate that the cause of the trouble is to be sought for in the intestine and that toxins there manufactured were seeds planted throughout his body for years before the demonstration of the present trouble. The order of events is well described by Lane⁶ who, writing of the consequences of stasis and toxemia, states that stasis is "delayed passage of the content of the intestinal canal of sufficient length to result in the production, in the small intestine especially, of an excess of toxic material and in the absorption into the circulation of a greater quantity of poisonous products than the organs which convert them are able to deal with. In consequence there exist in the circulation materials which produce degenerative changes in every single tissue of the body."

Cure or improvement of the diseases due to morbid conditions in the bowel may be brought about by limiting excessive fermentation and putrefaction and by removing the toxic decomposition products which would poison the bloodstream.

The quick and effective removal of these toxins by trans-duodenal irrigation, brings about a healthy condition in the intestinal tract, excessive fermentation and putrefaction is prevented, food and mucus no longer decay, digestion is completed, production of mucus and pus is gradually reduced, toxins are not formed in harmful amounts, the slow and insidious poisoning of the bloodstream ceases. The various organs and tissues of the body react to the improved condition of the blood, and because of the regulation of digestion and improved assimilation of food the whole body responds and the patient's general condition is improved, if he is not restored to health.

The treatment has been used with success in acute and chronic conditions in medicine, surgery, and the specialties. It can be used whenever it is desired to empty the bowels quickly and thoroughly, to stimulate peristalsis and physiological action of the abdominal viscera, to replace colonic irrigation, and in cases of vomiting of pregnancy and of postoperative ileus.

Cases treated by trans-duodenal irrigation are too numerous to be given in detail, but a statement of the conditions in which the writer and others have employed it will be of interest. The cases include ptomaine poisoning, enterocolitis, marked cases of ulcerative conditions, biliousness, chronic jaundice, many cases of intestinal toxemia and stasis, they include asthma, chronic bronchitis, migraine, neuralgia, pernicious anemia, secondary anemia, nephritis, rheumatism, rheumatoid arthritis, arterio-sclerosis (bloodpressure has been kept down 35 degrees below what it had been) endocrine disturbances, skin diseases, indicanuria. Then there were cases of intestinal parasites—pinworms and tapeworms that had resisted all other forms of treatment. Of surgical and obstetrical conditions the following have been treated: seven cases of marked postoperative ileus were saved (within an hour the patients were over their condition), several cases of incessant hiccup. In a number of cases of postoperative vomiting and in twelve cases of vomiting of pregnancy, a single treatment (at most two) cured the patient.

It will be of interest to know the opinions of a few writers who have had occasion to administer trans-duodenal irrigation. Bassler⁷ writes "Its employment is of distinct advantage in these distressing cases (pernicious ileus) and nothing in the postoperative handling of cases will bring more happiness." Levinson⁸ "I have practiced this procedure for two years both in hospital and private practice, and earnestly think it to be the method par excellence in the derangements of the alimentary system and the various toxemias." McDonald⁹ "This treatment has had the most extraordinary effect in all cases of toxemia of pregnancy which I have been able to treat. No patient has required more than a single treatment. In the beginning several patients had a number of treatments, because I did not believe it possible that one treatment would cure them." Aaron¹⁰ "This lavage restores normal physiology and if they are right who assert that the duodenum excretes a poison which is responsible for a great deal of the toxemia from which the human race suffers, then lavage according to this method is the remedy to remove the poison. Inasmuch as the intended result, the removal of intestinal stasis, is fully assured by this method, its general adoption is to be hoped.

THE RECOGNITION OF CHRONIC NEPHRITIS IN ITS EARLY STAGES, AND CONSIDERATION OF SOME NEGLECTED PRINCIPLES IN FUNCTIONAL DIAGNOSIS *

By NELLIS B FOSTER, M D,

NEW YORK

THERE exists, probably, no doubt in the minds of any of us that chronic nephritis is a common disease. Experience in practice as well as mortality statistics point to the fact. While heart disease heads the list of causes of death we all recognize that the myocardial insufficiency of middle life and cardiac failure are not rarely sequelae of chronic nephritis. But in spite of the prevalence of the disease the majority of cases are recognized when the disorder is far advanced and at a time when complications have already begun. The chronic nephritic of the hospital ward is an example. The disease is written on his countenance, treatment is restricted to palliatives and the prognosis measured in weeks or months. The tissue lesions as well as the complete history point to the long duration of the disease, years in most cases. And the chief reason that more cases are not seen early is probably the fact that until late, subjective symptoms are slight or absent and there is nothing definite to force the man to consult his physician. Unless opportunity afforded by some minor ailment be utilized by the physician for a general examination of his patient, chronic disease is likely to escape detection at an early period. Nowadays examination for life insurance discloses the majority of cases that are detected early, and the common grounds for refusing the applicant insurance in these instances is albuminuria, or vascular hypertension, or both. A person who has been rejected for life insurance is very apt to go directly and consult his physician. And right here there is not seldom an expression of divergent opinion. The physician sees a man who appears to be in robust health, he discounts the albuminuria, though he may confirm the test, and tells the man it is of no con-

sequence, a frequent finding, possibly fatigue, possibly he calls it a physiological albuminuria. But no careful study of the case is often made with a view of determining the cause of the albuminuria which, whatever its cause, is not a sign of health. And in passing it might be remarked that few men are convinced that insurance companies reject applicants on trivial excuses, so he consults another or several other physicians. Now the physician has based his opinion on an impression and possibly on the fatalistic idea that though he may be wrong nothing could be done. The insurance company, on the other hand, is acting on cold facts and statistics based on enormous experience. Just what does this experience indicate? Briefly this: persons having albumin in the urine at all ages have a death rate considerably above the normal, in early life albuminuria is as apt to portend tuberculosis as nephritis, but after thirty the mortality from nephritis in this group rises sharply, the death rate from nephritis of persons having a faint trace of albumin after the age of forty is ten times the normal, with a trace of albumin it is about thirty times the normal. In the face of this sort of experience no case of albuminuria may be lightly dismissed.

The other sign which should arouse suspicion is any abnormality of elevation of blood pressure. With the experience of a quarter of a century we have accurate figures for the range of normal, and this range is not wide. It is quite true that studies are on record indicating that a considerable departure from the average range is occasionally noted in robust athletic young men, but this proves nothing for us until we know the full life history of these young men. Possibly in this group there will be found a special predisposition to early

* Read to the Section on Medicine at the Annual Meeting of the Medical Society of the State of New York

† Report of the Joint Committee on Mortality of the Association of Life Insurance Medical Directors, New York, 1925

vascular disorders. At any rate there are ample data available,[†] based on seven hundred thousand cases. This data signifies that the average range of blood pressure in healthy adults between the ages of 18 and 60 is from 120 to 135 mm. of mercury systolic and 75 to 85 diastolic. Furthermore an elevation of 5 to 15 mm. in the systolic or 10 mm. in the diastolic pressure is accompanied by an increase in mortality of 14 to 16 per cent. Facts of this character are worthy of deep thought. They do not, however, offer any tangible support for the easy optimistic attitude which we are apt to take in regard to apparently slight departures from a rather narrow normal range.[‡] It is not my implication that either traces of albumin in the urine or slight elevations of vascular tension are invariably significant of nephritis or even of grave disease. These are signs which should awaken suspicion. They must be explained if persistent. A subnormal temperature in the morning or a slight pyrexia in the evening are not signs of tuberculosis though we quite properly have some apprehension in these cases and give them due study. This should be our attitude in instances of albuminuria or hypertension of doubtful origin.

At the present time the etiology of chronic nephritis is obscure. We are asked to regard the disease as due to heritable factors, there is evidence in support of this hypothesis, it is pointed out that the disease is likely a result of infections or toxins and there is evidence for this hypothesis also. But there is yet no proof which compels us to accept any hypothesis. Since the progress of this disease is attended by ever increased complexity as various organs and tissues are involved (arteries, heart, etc.), it would seem that etiology can be studied only in the early stage of the malady. This demands first that we recognize it early. Then too if anything avails in diet adjustments in removing infected foci, in arranging a healthy mode of life, these are more apt, certainly, to produce beneficial results before tissue destruction has transgressed the factor of safety.

But the question of diagnosis is not settled. Albuminuria and hypertension serve to arouse suspicion but not to settle the question of diagnosis. Nor do the presence of casts in the urine, though they are important as evidence. The study of casts has fallen into neglect, though it seems now to be reviving. It is to

be remembered that casts disintegrate quite rapidly in alkaline urine, therefore specimens which have undergone ammoniacal decomposition are worthless. It is best to have the sample voided into a bottle containing thymol or boric acid. The number and character of casts too, is much better learned if the urine is concentrated and on this account the examination for casts is advantageously made on specimens of urine during the concentration test (see below).

In the present deficient state of our knowledge it is hardly possible to arrive at a correct diagnosis in the early period of chronic nephritis without recourse to some functional tests. But not every functional test will help. The phenol-S-phthalein test for example, probably the one in widest general use today, is quite useless until renal degeneration is well advanced. The usual modes of applying concentration tests, while quite useful in confirming clinical impression in advanced cases of nephritis are of no help in early cases since there is in these cases no obvious tendency to a fixation of specific gravity of the urine and the normal range of 1.010 to 1.020 is easily met.

It is quite easy to understand why it is so difficult to devise satisfactory functional tests for organs like the kidneys, liver, and heart if one but recalls the enormous factor of reserve in these organs. Only the severest strain taxes this reserve in health. One kidney may be removed with safety if the other be healthy, and there is no ill effect for the patient. In other words, man is born with twice as much kidney tissue as he needs. We have found that it is only through tests which impose a maximum strain upon renal function that we were able to detect any difference at all between persons having two healthy kidneys and persons who had suffered the loss of one kidney. This fact is significant, it seems to me, since in estimating function we have to think in terms of functioning glomeruli and tubules. Is there so much difference between the person who has lost half his glomeruli and tubules by disease and this other person who has lost half of his by surgical removal of one kidney? In view of my own studies I am dubious of our ability to detect by functional tests alone an impairment of the kidney which involves no more than half the glomeruli.*

In view of this enormous reserve, this factor of safety, it becomes evident that early and relatively slight lesions will become manifest only under a severe strain. We must devise tests with this fact in mind. Next, since the activity of kidney excretion is directly dependent on the circulation, we must be on our

[†]The more recent studies concerning the arterial tension in young persons are of great interest in their bearing upon hypertension. They suggest that the disorder may be a constitutional state, sometimes at least congenital. All these studies agree in the observation that a small percentage of young persons have abnormally high arterial tension, the incidence of the abnormality is about 5 to 10 per cent. The most recent study that of Lord Dawson of Penn was made on school children from 10 to 17 years of age. Of 650 52 (8 per cent) showed a hypertension. (*Brit. Med. Jour.* 1926 Jan. 30 p. 190). See also Diehl & Sutherland *Arch. Int. Med.* 1925 36 p. 151. Alvarez, *idem* 1923 32, p. 17. Weitz *Zent. f. Klin. Med.* 1922, 96 p. 151.

*Foster N. B. Renal functions in persons having only one kidney, *Arch. Int. Med.* 1925, 36, 884.

guard that defects attributable apparently to the kidney are not in fact defects of the myocardium

The primary essential for the excretion of salts through the kidney is the ability to excrete water. When a normal man drinks a liter and a half of water before breakfast he will void a liter or more of urine during the following four hours. If less is voided either the kidney function or the myocardium is abnormal. In a small percentage of cases of quite early nephritis this test discloses no abnormality. We call this a water excretion test.

The ability to excrete the necessary solids in a highly concentrated form is characteristic of the normal kidney. As nephritis progresses this ability becomes more and more impaired until in the later stages of the malady the specific gravity becomes "fixed," as we say, within narrow limits. But in the early stages it is possible to show a loss of power of concentration only when a sufficient strain is imposed to demand either maximum concentration or failure of excretion. This condition of functioning under most adverse conditions is secured by withholding water. The patient receives no water, soup, milk, tea, or coffee, no liquid except that contained in ordinary food, for twenty-four hours. The test is begun after breakfast and continued until breakfast of the next day. The specimens of urine are collected separately as voided, the most significant being the voidings after four o'clock, during the night and the last specimen before terminating the test. With normal persons the specific gravity of the various specimens gradually rises during the period of the test and customarily reaches a maximum of over 1.030, not rarely 1.034 or 1.036. In nephritis there is a failure to attain this degree of concentration, depending roughly on the extent of the lesion. These highly concentrated specimens are also best suited for examination for casts.

Formerly we tested these concentrated specimens for the percentage of urea in them, but this has been abandoned largely since the results were not in accord with clinical evidence nor confirmed by experience.

A considerable experience covering careful study of many cases and many tests has brought us finally to this relatively simple procedure and though leaving much to be desired, it does enable us to detect nephritis at an earlier period than formerly.

I wish now to show a few charts which summarize at a glance the results of studies of cases. These cases have been selected as examples of types of disorder and examples also of the problem often presented.

NEPHRITIS TESTS

Normal

Physical Examination

Fundus oculi hemorrhage, 0, exudate, 0, oedema, 0.
Arterio-sclerosis, 0, neuritis, 0

Heart hypertrophy, none, hypertension, syst. 124, diast. 74

Oedema face, none, back, 0, legs, 0

Laboratory Examination

Urine albumin, 0, casts, 0, leukocytes, 0, blood, 0

Blood urea N, 11 mg, uric acid, 37 mg

Phenol-S-phth recovered in 2 hours, 58%

Water-fast specific gravity night urines, 1.024, 1.028, 1.036

Water-excretion volume of urine in 4 hours, 1180 c.c. Lowest sp. gr., 1.001

The first chart summarizes the study of a normal young man. We have several hundred of these normal controls to prove that the tests are not too drastic.

NEPHRITIS TESTS

Orthostatic Albuminuria

S L—age 31

Physical Examination

Fundus oculi hemorrhage, 0, exudate, 0, oedema, 0

Arterio-sclerosis, 0, neuritis, 0

Heart hypertrophy, none, hypertension, syst. 110, diast. 68

Oedema face, 0, back, 0, legs, 0

Laboratory Examination

Urine albumin, ++, casts, 0, leukocytes, 0, blood, 0

Blood urea N, 12.6

Phenol-S-phth recovered in 2 hours, 59%

Water-fast specific gravity night urines, 1.022, 1.028, 1.032

Water-excretion volume of urine in 4 hours, 1090 c.c. Lowest sp. gr., 1.002

The next case illustrates a rather common problem. This patient was 31 years of age, of slender build, apparently healthy, but not robust. He had been refused insurance on account of albuminuria. The general examination gave no data indicating any disease. Albuminuria was present and pronounced. He was instructed to send samples of each urine voided, to void before going to bed and again *before* he got up. This was continued several days. None of the night urines contained albumin. A few more tests were sufficient to confirm the diagnosis of orthostatic albuminuria. It is not a rare disorder, it is not nephritis and should not be confused with it.

NEPHRITIS TESTS

Tuberculosis

M C—age 33

Physical Examination

Fundus oculi hemorrhage, 0, exudate, 0, oedema, 0

Arterio-sclerosis, 0, neuritis, 0

Heart hypertrophy, 0, hypertension, syst. 124, diast. 75

Oedema face, 0, back, 0, legs, 0

Laboratory Examination

Urine albumin, ++, casts, 0, leukocytes, 0, blood, 0

Blood urea N, 9.8

Phenol-S-phth recovered in 2 hours, 62

Water-fast specific gravity night urines, 1.026, 1.030, 1.032

Water-excretion volume of urine in 4 hours, 1130 c.c. Lowest sp. gr., 1.002

The next case (Case 3) came under observation three years ago. The patient was referred as a case of nephritis on account of the pronounced albuminuria. Since there was no oedema it could hardly be a case of nephrosis and the evidence gave no support to the idea of nephritis. On this account tuberculosis was suspected, and this suspicion was borne out by subsequent events. Following an acute infection, possibly influenza, definite signs developed in one lung and the patient spent a part of a year at Liberty, where tuberculosis was finally demonstrated. Then there was a year of fair health but finally a recrudescence of the old process. There was never evidence of tuberculosis of the kidneys. This case is an instance confirming statistics that albuminuria in early life often portends tuberculosis.

NEPHRITIS TESTS

Nephritis

J F—age 37

Physical Examination

Fundus oculi hemorrhage, +, exudate, +, oedema, 0
Arterio-sclerosis, +, neuritis, 0
Heart hypertrophy, +, hypertension, syst 195, diast 110

Oedema face, 0, back, 0, legs, 0

Laboratory Examination

Urine albumin, +, casts, +, leukocytes, —, blood 0
Blood urea N, 22

Phenol-S-phthl recovered in 2 hours, 35%

Water-fast specific gravity night urines 1017, 1017, 1017

Water-excretion volume of urine in 4 hours, 880
Lowest sp gr, 1005

It will assist you now if I show a chart summarizing the data in a typical case of chronic nephritis. This man is typical in every respect and one might recognize the nature of his malady by inspection alone. This examination was made about eighteen months ago, the patient is still alive though unable to pursue his vocation. The significant facts were albuminuric retinitis, vascular hypertension, albuminuria, cylinduria, nitrogen retention and a failure of concentration above 1017 (note the fixation at this point), and lowered water excretion. Nephritis is too often first recognized as this stage when the outlook is hopeless and therapy reduced to palliatives.

NEPHRITIS TESTS

Nephritis

E F—age 31

Physical Examination

Fundus oculi hemorrhage, 0, exudate, 0, oedema, 0
Arterio-sclerosis, ±, neuritis, 0
Heart hypertrophy, 0, hypertension, syst 130, diast 90

Oedema face, 0, back, 0, legs, 0

Laboratory Examination

Urine albumin +, casts, +, leukocytes, 0, blood, 0
Blood urea N, 13.3, uric acid 4.6
Phenol-S-phthl. recovered in 2 hours, 54%

Water-fast specific gravity night urines, 1024, 1027, 1026

Water-excretion volume of urine in 4 hours, 790
Lowest sp gr, 1004

The next case represents about as early a stage of nephritis as we are able to recognize with some degree of confidence. This man supposed himself in health until he was forced to pay excess premiums for life insurance. He also appeared perfectly healthy. Examination revealed two departures from normal, a diastolic blood pressure 10 mm too high, a definite though slight restriction of renal function both of concentration with a maximum specific gravity of 1027 and of water excretion. Repeated examinations and the gradual progress of the disorder have confirmed the diagnosis.

The question is often asked: But are not these tests too exacting? May they not disclose lesions which are really of slight importance? There are two facts which answer these objections, first, young healthy adults meet the requirements of the tests, second, persons with one healthy kidney meet the requirements of the tests. This latter fact might seem to imply that so far as functional tests go we are unable to detect a limitation of function until half the kidney tissue is destroyed. I am not sure but this is true.

NEPHRITIS TESTS

One Kidney

Physical Examination

Fundus oculi hemorrhage, 0, exudate, 0, oedema, 0
Arterio-sclerosis, 0, neuritis, 0
Heart hypertrophy, 0, hypertension, syst 124, diast 68

Oedema face 0, back, 0, legs, 0

Laboratory Examination

Urine albumin, 0, casts, 0, leukocytes, 0, blood, 0
Blood urea N, 18.4

Phenol-S-phthl recovered in 2 hours, 56%

Water-fast specific gravity night urines, 1036

Water-excretion volume of urine in 4 hours, 970
c.c. Lowest sp gr, 1002.

The methods of examination which have been outlined are by no means perfect. There are many cases of course, concerning which it is impossible to formulate an opinion. This is so in medicine generally, but the methods here described have two considerations in their favor. They enable us to get a better idea of the individual case than any other mode of study that I have experience with, and second, the tests are so simple that they can be carried out anywhere.

Our present knowledge of the etiology of the various types of nephritis is very defective. Only by the recognition of the disease at an early period is knowledge likely to be advanced, and the first step in this direction is more refined methods of diagnosis than have been used heretofore.

KIDNEY FUNCTION TESTS

By JOHN A. LICHTY, M.D., Clifton Springs, N. Y.

A Discussion of the Paper of Dr. Nellis B. Foster, read before the State Medical Society, March 31, 1926

That the paper which Dr. Foster has presented is a timely one, all must admit. For a quarter of a century past there has been a tremendous amount of medical literature accumulating, giving evidence of the intense desire to interpret kidney function. In this activity there is evidence of two definite lines of research relative to the function of the kidney. One is in the direction of correlating kidney disease, as it is seen clinically, with kidney pathology, as it is found at the post-mortem. We are all acquainted with the apparent satisfaction which usually follows some new and promising classification of the nephritides and the application of a new test. Then again we are, also, acquainted with the astounding difficulties which the problem presents.

The other lines of research is in the direction of developing a test whereby the very earliest manifestation of disturbance of kidney function may be recognized. It is in this line that the paper just read has probably advanced our knowledge to a considerable degree. In a satisfactory consideration of the supposed case of Bright's disease it is necessary to know the very earliest manifestation of disturbed kidney function, and it is just as necessary to know the extent of the damage which the kidney has sustained. It appears to me from the standpoint of the present endeavors in preventive medicine, the first is of the greater importance. This paper appeals to me, therefore, all the more because it applies to the early detection of disturbed kidney function. The method proposed by Dr. Foster is simple and practical. No elaborate laboratory equipment is necessary.

No unusual technical skill is required. It seems to me practical and applicable to the daily routine of the practice of medicine. In a rather extensive consultation practice I have frequently been amazed at the neglect of the more simple tests of the urine. This neglect is chiefly, I believe, because the average practitioner is so impressed with the elaborate procedure proposed for examination of urine, blood, etc., that he passes them by and at the same time looks upon the more simple tests as being unreliable. This is the excuse for neglecting to examine the urine.

It is interesting to note that Dr. Foster harks back to the more simple principles which were recognized first by Richard Bright a century ago in his epoch-making studies of disease of the kidney.

In the Clinic at Clifton Springs, Dr. Roger Hubbard, of the Biological Department, has followed closely all the tests of urine, blood, etc., proposed to determine the early qualitative and quantitative impairment of kidney function. In some respects no test has given more reliable information than the well known "fixation and concentration test."

The test proposed by Dr. Foster today suggests a fine technique of this familiar test. It seems to me to promise more accurate and dependable information. It will be interesting to note after a year or two of experience with it, what the general verdict will be as to its reliability in furnishing earlier information than has heretofore been possible as to the change of kidney function.

DISTRICT BRANCH MEETINGS

This year for the first time, there has been a careful survey of the resources available for the fall meetings of the Eight District Branches

Accounts of preliminary meetings, in every District Branch are printed on page 687 of this Journal. The results of this careful planning should be that the meetings of the District Branches will be more practical and fruitful than ever before

The District Branches occupied a large place in the plans of the reorganizers of the Medical Society of the State of New York. Many

Branches are as large as some State Societies and their responsibilities and opportunities are correspondingly great

The State Society and the sixty County Societies have made great progress during the past year or two, and the time has now come when the District Branches should show the same progress in the evolution of organized medicine. The preliminary conferences constitute an essential step in the forward movement of strengthening and perfecting the plans of physicians throughout the State of New York

THE MEDICAL RESERVE CORPS OF THE ARMY

This is the season when outdoor camps flourish. The Scouts, both boy and girl, take to the woods and lakes and seashores, there to live the simple life and revert to an elemental form of life where strength and physical progress are at a premium, and life is divested of its superfluities and non-essentials.

Boys go to Citizens Military Camps at Government expense in order to learn the fundamental principles of national defense, and grown men, veterans of the World War, submit themselves to camp schools, where they may learn and practice the newer methods which will be put to use in time of national emergency.

The August, 1925, issue of this Journal contained a description of the Medical Reserve Corps by Lt Colonel Charles R. Reynolds, Commandant of the Medical Field Service School at Carlisle Barracks, Pennsylvania. This school conducts two courses of two weeks each for officers of the Medical Reserve Corps of the Army of the United States. The second course this year was given from July 4 to 18 inclusive and was attended by 229 physicians, 77 dentists, 13 veterinarians, 5 chaplains, and 52 specialists such as laboratory experts, sanitary engineers and medical supply officers. Of these, 109 were from New York State. There were also 380 medical students belonging to the Reserve Officers Training Corps—the R O T C—who will be commissioned first lieutenants when they graduate from their medical, dental and veterinary schools. These two units formed a body of 760 men—as many as were in the number of medical officers, both regular and reserve, at the outbreak of the World War. As the war progressed, more and more medical men were enrolled until the medical officers numbered 31,000 and about one-sixth of the physicians in active practice were in the army.

The World War demonstrated the great need of medical officers and their essential usefulness. A wounded man in a battle line is far more demoralizing than the shells of the enemy, and should be removed from the front as quickly as possible for military as well as humanitarian reasons. Then, too, the medical men are essential in preserving the health and strength of the soldiers, and to this end the medical men are given rank and power equal to those of the officers of the infantry, artillery, and engineers. This is in great contrast to conditions at the beginning of the war when a medical officer was merely tolerated and was expected to confine his work to the treatment of the sick and disabled.

Preventive medicine is exemplified at its best in the army. There the men are examined at frequent intervals and physical defects are

corrected in their incipency. Food and diet are supervised, cleanliness is enforced, and the mode of life is regulated. The periodic health examination is carried on in its highest efficiency, and its application is made mandatory. Yet whenever a large number of men are gathered under the best of conditions, a considerable proportion will be disabled and unable to perform active duty. There will be accidents, and stomachaches, and attacks of appendicitis and other diseases, as in civil life. From two to three per cent of the men in any command will be under the doctor's care continuously. This was true in the Medical Field Service School where every man had to pass a rigid physical examination as a requisite for admission. But while some medical and surgical conditions are sure to develop, yet their number may be reduced to a minimum. It would seem that two or three per cent is the irreducible minimum for soldiers living under peace conditions, and the proportion will be doubled and tripled among soldiers in the field under war conditions.

It is a liberal medical education to attend a summer camp of soldiers and observe the medical service under field conditions. Those conditions are well known, and may be foreseen and controlled. There preventive medicine may be seen in actual operation, and its principles grasped in concrete form. An army camp is one of the best of schools for training a sanitarium and health officer.

The Medical Field Service School at Carlisle is the West Point of the Medical Department of the Army of the United States. It trains professional men for all branches of medical service. All those attending the school, both the physicians and those not yet graduated submit themselves to army discipline which means that they live under conditions of camp life. The officers as well as the R O T C students were quartered in tents where they undergo the routine of military service as distinct organizations, provisionally formed for training purposes.

The experience gained in the school is of great service during emergencies in civil life as well as in war. There are likely to be fires, storms, floods, explosions, train wrecks, strikes and also panics and epidemics, whose control requires quick thinking, and a knowledge of how to command men. Doctors are the natural leaders in all these conditions, and often they are the only leaders in the emergencies. If boy scouts are of value in teaching first aid and self-reliance, then the Medical Field Service School is of still greater public value in providing leaders to conserve and preserve health and life.

What did the men do in the Medical Field

Service camp? They went to school, and did about all the things that boys do in a school camp. They drilled for an hour every morning, attended classes for five hours, and did problems in the field on two days of each week. They played ball and pitched horse-shoes, published a camp paper, held reunions of their former regiments and colleges, and went to church on the parade ground on Sunday. They also made a tour of the Battlefield of Gettysburg. Every moment was taken up and time passed as rapidly and as happily as in a recreation camp.

A striking feature of the camp was its democracy. Colonels and second lieutenants were equal, for all were learners. The lieutenants played ball and led the social life, and the colonels showed the younger men how to run ambulances and do the administration work of the larger units.

The school was conducted as nearly as possible under conditions like those of an army in the field. A battle demonstration was staged with guns, and bombs, and airplanes, and smoke-screens, the R O T C boys picked up the wounded, gave them first aid, carried them back to first aid stations from which they were carried in ambulances to the hospital five miles to the rear.

Another exercise was that of map reading and of locating aid stations and hospitals, and laying out ambulance routes as in actual battle.

The Medical Field Service School is an essential part of the system of national defense and preparedness for emergencies. Emphasis is placed on the word "Field."

Professional men in private life are familiar with all phases of the practice of medicine among private patients and in institutions and business houses, but the U S Army is almost the only institution that affords training for great emergencies, when entirely novel situations must be met. An emergency will not give rise to a panic when a large body of men are trained to handle the situation.

Physicians and dentists will form the largest class of professional civilians who will be called into the army in the time of great national emergency. At least one-fifth of their number will be needed in active service in the army and navy. Their number will probably exceed that of all other professional men combined. They alone of all professional men will be needed in very great numbers. There is a grave duty imposed on physicians, dentists and veterinarians to serve in the army in a professional capacity in the next war. The Medical Field Service School has already trained about 2,000 men for army service and the number of applicants are far greater than can be taken under existing appropriations. It is to the great credit of the medical dental and veterinary professions that practitioners are willing and anxious to do their part in national preparedness.

HARMONY

"Yielding much for the sake of harmony," is a frequent confession for which credit is often claimed. Just what is meant by that expression?

Every doctor who belongs to a medical society unconsciously makes a list of his principles and beliefs. When these lists are compared, many items are found to be identical, and others are divergent or contradictory. Those doctors who hold the same belief in any line are likely to form a medical group or society for the purpose of promoting that particular tenet, and they agree to disagree in regard to other matters.

The members of the Medical Societies of the States and Counties are remarkably unanimous regarding a large number of items of belief, and they are equally divergent in re-

gard to other subjects. All doctors, for example, agree that physicians should make their influence felt in public health, and should participate in the activities promoted by lay organizations, but when it comes to the details of the participation and cooperation, should the doctors work for, or with, or over the lay organizations? It is in the decision regarding these secondary questions that doctors pose as either martyrs or dictators. If martyrs, they are prone to quote their martyrdom as sufficient ground to assume the role of dictators. "I have yielded enough of my principles, and now I will resign if I can't have my own way." Does this have a familiar sound?

Martyrs and dictators in medical societies have much in common, and are often interchangeable characters.

A GUIDE FOR PHYSICIANS

New York City has a wealth of clinical material which is at the service of physicians who seek information. It also has experts who are willing and anxious to impart their knowledge to visiting physicians. How to bring the teachers and pupils together has been seriously considered by the New York Academy of Medicine.

The Academy has issued a booklet of 80 pages entitled, "Opportunities for Clinical Study in Hospitals in New York City." It contains a list of the hospitals of Greater New York and classified information regarding the kind of instruction which a physician can obtain in each. It gives a detailed account of the clinics and classes which are held in each hospital, and the names of the instructors with the days and hours of their lectures.

The booklet also gives maps showing the

location of each hospital. It contains a full index of the courses and one of the clinical teachers.

The booklet will be sent free on application to the New York Academy of Medicine, 17 West 43rd Street, New York City. In addition physicians who call at the Academy will find lists of operations and clinics posted, and will be given a glad hand and further information that he may desire.

The Academy of Medicine is entering upon a greatly enlarged field of usefulness. It has the trinity of equipment, personnel, and endowment, and its facilities are at the disposal of visiting doctors. It is the desire of the managers to make the Academy a medical center at which physicians from any locality may obtain the information regarding medical practice.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

The New York State Journal of Medicine for August, 1901, contained an article on "The Technique of Bloodless Works," by Robert H. M. Dawbarn, M.D., of New York City. The doctor proposed the elimination of blood from a limb previous to operating by means of bandages wrapped tightly around the part, and also the opposite procedure, that of holding the blood in a limb in order to keep it from an affected part—brain, or lung, or stomach, or other internal organ that was bleeding.

Dr. Dawbarn's method was extensively tried in the hospitals of New York City during the decade of the nineties and its usefulness and limitations were determined. However, the method never became generally used and is scarcely mentioned today. Yet there is no doubt of its usefulness in certain conditions.

A novel suggestion is made. When an elbow is injured, encircle the limb with a bandage applied tightly, beginning at the fingers, and running to the shoulders, and then remove the bandage, beginning at the other end but keeping a few turns at the upper end of the limb. This will eliminate both the blood and the extravasated serum from the joint and will enable the doctor to feel all the bony parts as distinctly as on the well limb. The x-ray has removed the necessity of this procedure.

Dr. Dawbarn also suggests bleeding into the limbs in cases of apoplexy. The method is to use three limbs, and to encircle them with bandages which will cut off the return venous circulation while permitting the entrance of blood through the arteries. Dr. Dawbarn claims that several quarts of blood may be retained in the limbs by this method.

The fourth limb is to be utilized after a half hour and one of the three first used is to be released. In this way the limbs are to be used in rotation. Dr. Dawbarn says of the method:

"This same idea of constricting the extremities enables one to do comparatively bloodless surgical work upon the trunk, face, neck, or brain, and is worthy of more frequent usage than at present. It also is unquestionably the best, indeed the only reliable method of treating medical hemorrhages—as distinct from surgical ones. By a medical hemorrhage I mean one where direct mechanical control is out of the question—hemoptysis, hematemesis, and apoplexy, for example. It is a curious fact that this best of all methods—and a very old one—has been completely lost sight of by most practitioners."

MEDICAL PROGRESS

Diagnosis and Treatment of Infections of the Biliary Tract.—A T Basin (*Canadian Medical Association Journal*, June, 1926, xvi, 6) asserts that usually acute cholecystitis is an *accident* supervening upon a chronic cholecystitis, and it is to the antecedent condition that we must give close ear. Fat, flatulent women above forty, and particularly those of unusual fecundity, are the special victims of gall-bladder disease. Important in diagnosis is a history of chronic dyspepsia not relieved by lying down. Physical signs are often few. In the writer's experience Boas' sign is seldom present, whereas a tender epigastrium and Robson's point are of great diagnostic aid. Pain in the scapular region, which is readily explained by the nerve distribution, must not be confused with phrenic nerve reflexes, such as occur in diaphragmatic pleurisy, subdiaphragmatic abscess, or ruptured spleen. There is no direct evidence that the phrenic nerve supplies the gall-bladder or biliary passages. Gastric analysis occupies a position of inferiority in diagnosis. Visualization of the gall-bladder by means of sodium tetrabromophenolphthalein, or sodium tetraiodophenolphthalein gives results, on the whole, reliable and satisfactory, and the roentgenological examination may serve to eliminate other possible causes of the symptomatology. The finding of bile in the urine is of definite help, but a negative finding is of no value whatsoever. The only value of the Van den Bergh test is the gaining of time, or the detection of such slight blood contamination as would escape observation in uranalysis or tissue staining. The Meltzer-Lyon test may be abandoned for diagnosis and especially for treatment.

The determination of pancreatic dysfunction (hyperglycemia or diminished sugar tolerance) is highly important. In the Montreal General Hospital hyperglycemia was found in 75 per cent of all cases of lesions of the biliary passages. Axioms which govern Bazin's procedure are (1) Remove all other foci of infection. (2) With biliary infection apparently limited to the gall-bladder, cholecystectomy without drainage is indicated. (3) With evidence of more diffuse infection, cholecystectomy with drainage of the common duct is indicated. (4) If infection of the gallbladder is presumably the cause of symptoms, and if, after opening the abdomen, other viscera are found to be normal, and to the casual observer the gall-bladder may appear normal, cholecystectomy is still indicated. The signs of early and slight infection of this organ

are subperitoneal deposit of fat, especially along the lines of the vessels in the wall, and palpable lymph glands in the gastrohepatic omentum, or on the neck of the gall-bladder. Further study of hepatic and pancreatic function may lead to the conclusion that the early eradication of chronic biliary infection will lessen the incidence of diabetes.

Gallstones.—After discussing the etiology and symptoms of gallstones, cystic-duct stones, and stones in the common bile duct, R. P. Rowlands (*Practitioner*, June, 1926, cxvi, 6), emphasized the importance of differentiating cholecystitis from appendicitis (especially when the appendix is placed high up), renal colic, and gastric and duodenal ulcer. Biliary dyspepsia has no time relation to food, there is achlorhydria in at least one-half the cases, hypochlorhydria is rare, while in duodenal ulcer, over-acidity and hunger pains are almost constant. The *x-ray* examinations are valuable in excluding evidence of gastric and duodenal ulcer, and occasionally showing the shadow of gallstones. Examination of the duodenal contents, by means of a Ryle tube, often helps, pus cells were found in 58 per cent of the cases examined at New Lodge clinic, and cholesterol crystals in 50 per cent. When stones obstruct the bile duct this evidence is not available. Excess of cholesterol in the blood is also of some value, for more than 0.15 per cent affords additional evidence in support of gallstones. The gall-bladder is usually found to be enlarged when the attacks are due to gallstones, except when blockage of both cystic and common bile ducts exists. Those predisposed to gallstones should avoid foods known to be rich in cholesterol. In the medical treatment, dieting along these lines and the use of antiseptics, such as sodium salicylate, 10 to 20 grains three times a day for months at a time, are indicated. Methenamine, given according to the plan outlined by Hurst, is the best antiseptic. It must be stopped at once, however, if any cystitis or hematuria is noticed. Olive oil and belladonna may relieve the gastric symptoms by diminishing gastric acidity and allaying pain. Operations for gallstones should not be undertaken lightly. Whenever possible, if the disease is limited to the gall-bladder, especially in young persons, cholecystectomy is preferable to cholecystotomy, the mortality being less and the results infinitely better. The common duct should not be operated upon during an acute attack of jaundice and especially of fever, as in this case

the risk of death from hemorrhage, liver shock, suppuration, or cholemia is very real. Preliminary careful preparation with injection of calcium chloride, with plenty of water and glucose by rectum, adds greatly to the safety of the patient.

Treatment of Cholecystitis and the Prevention of Gall Stones—In the diagnosis of gall-bladder and common bile-duct disease, Arthur F. Hurst (*Lancet*, May 22, 1926, ccx, 5360) states that in his experience [contrary to that of Basin above noted] the Meltzer-Lyon test yields very valuable information, as do other biochemical tests and cholecystography. The treatment consists in dealing with the infection by biliary antiseptics, autogenous vaccines, the removal of septic foci, and the provision of adequate biliary drainage. As a biliary antiseptic he recommends large doses of methenamine which are well tolerated if the urine is kept alkaline. The mixtures used are a dram each of sodium bicarbonate and potassium citrate in an ounce of water, and 100 grains of urotropine in an ounce of water. The first day an ounce of the alkaline mixture is taken with half an ounce of the urotropine mixture, the dose of the latter is increased by a dram each day until a full ounce is taken. As a rule, the patient can take 100 grains of methenamine three times a day without difficulty. If achlorhydria is present from 1 to 2 drams of dilute hydrochloric acid should be taken in 5 to 10 ounces of water to which the juice and pulp of an orange and some sugar are added. The first dose is taken a half hour before breakfast, and as a beverage at lunch and dinner. If the bile obtained through the duodenal tube contains pathogenic microorganisms, a vaccine should be prepared and a course of inoculation carried out for several months. J. F. Venables has proved conclusively that concentrated magnesium sulphate solution given by mouth acts as efficiently as when introduced into the duodenum. The patient should take, each morning upon awakening, as large a dose as he can without producing diarrhea. Biliary drainage is promoted by active outdoor exercise and by abdominal exercises. As a prophylactic measure, an effort should be made to keep down hypercholesteremia in normal pregnancy by prohibiting eggs and cream which contain a great deal of cholesterol. Patients with active cholecystitis should take a diet poor in cholesterol, avoiding in addition to the yolk of eggs and cream, brain, liver, sweet-breads, kidney, and roe, all animal fats should be taken in moderation. If the patient is extremely thin olive oil may be given before meals, especially if hyperchlorhydria is present, as it inhibits the flow of gastric juice and causes the gall-bladder to

contract, thus promoting drainage. Hurst questions whether within the next ten years cholecystitis will not be treated so efficiently that operations on the gall-bladder will become rare events.

Peroral and Intravenous Cholecystography—K. Presser reports the results of Holzknecht's experience with this new American resource in the following summary of conclusions: (1) It may be shown that the gall-bladder is normal and we can thereby exclude this organ in differential diagnosis. (2) Abnormal situation of the gall-bladder may be shown. (3) Obstruction of the cystic duct and contracted gall-bladder may be shown. (4) One may demonstrate the presence of pathological situations and alterations in form of the gall-bladder. (5) When a contrast material is injected intravenously pathological alterations may be shown in the wall of the gall-bladder. (6) The method increases the visibility of concretions which contain no lime and do not cast shadows on the roentgenogram, because these formations appear as clear areas.—*Wiener klinische Wochenschrift*, June 17, 1926.

Transition of Aortalgia Into Angina Pectoris—Norbert Ortner relates a case which he was able to follow up for four years which throws light on the subject of vague substernal pain passing into the crises of angina pectoris. The patient was a man of 50, a heavy smoker, who first complained of the substernal pain when it was mild. It gradually became more severe and was aggravated by physical exertion or mental excitement. After persisting several years the pain began to radiate down the left arm, so that the patient became unable to work, for every effort started the pain. At this juncture the symptom took on a paroxysmal character with the pallor, cold sweats, and vertigo of angina pectoris, the patient being forced to lie quiet, not even daring to take a deep breath. Ortner, when he first examined the patient in the initial period, found an aortic systolic murmur with accentuated second sound. Several years later these symptoms were aggravated and there was in addition a mitral murmur with cardiac dilatation. He estimates the case as follows: At first there was a localized atheroma of the aorta at the level of the coronary orifices, where a simple tension pain developed. The degenerative process gradually extended into the coronary arteries and when these became obstructed the crises of angina developed. The mitral lesion and dilatation arose when the atheromatous process reached the valves, but evidently had nothing to do with the clinical picture.—*Medizinische Klinik*, May 21, 1926.

Prognosis of Angina Pectoris—F Kisch has studied the subject of prognosis in connection with 132 patients and finds that it must differ much with the type, and accordingly he isolates three types as follows. First a group of relatively recent cases in which the paroxysms are determined by the patient's movements and by taking food. The crises are short and the malaise which accompanies them passes off with the symptoms. Radiating pain is limited to the left side. In such cases the diaphragm may be high placed, so that the heart and aorta are somewhat crowded. To control these attacks we require only nitroglycerin and measures directed against meteorism. In these patients the prognosis for life is good, nothing being said of any other prognosis. The second type is much like the first, but the state of the stomach is not a factor. Even though the crises may be frequent and severe they are not protracted, and the prognosis for life is good again. In the third group the paroxysms are of long duration and the malaise continues after they have passed. Radiation is not restricted to the left side and the radiating pains may be very intense. Attacks are not only precipitated by motion and taking food but occur even when the patient is seated or lying and irrespective of the filling of the stomach. In this type of case the blood pressure may be falling. The prognosis for life is not good.—*Medizinische Klinik*, May 21, 1926

Auricular Flutter—In order to illustrate the method of treatment and to show the importance of early diagnosis of auricular flutter, Louis Faugeres Bishop (*Medical Journal and Record*, June 16, 1926, cxxiii, 12) describes the case of a woman, 51 years of age, with signs of cardiac decompensation with complete exhaustion. There were cyanosis, ascites, very rapid heart rate (216 to the minute and regular) and extreme nausea. Digitalis had been given casually. The situation was desperate and it was probable that auricular flutter was present. Two ampoules of digifolin were at once injected intramuscularly, followed every hour by a single ampoule, until eight ampoules had been injected. At about the time the eighth ampoule was given the pulse rate fell to 40 and was completely regular. The dose was then reduced to three ampoules in twenty-four hours, with further reduction when the pulse rate, which had again risen, fell to 90. With the control of the heart the nausea and vomiting disappeared. There is no reason why a patient of this type, with the heart, arteries, and kidneys apparently sound, should not enjoy fairly good health with a controlled fibrillation, or possibly with complete restoration of rhythm. Digitalis is a specific remedy

for auricular flutter. It acts by first changing the flutter to auricular fibrillation and then normal rhythm may return. On account of its rather grave significance it is important to recognize auricular flutter in order that proper treatment may be instituted without delay. Positive diagnosis can be made only by the electrocardiogram, but in a person suffering from cardiac failure, with extremely rapid through regular ventricular rhythm, the possibility of auricular flutter should always be considered. The intravenous or intramuscular administration of digitalis is not contraindicated in the presence of nausea and vomiting in cases of this kind. It is well to remember that in auricular flutter the heart is not condemned as a whole, but the auricle is particularly affected. The establishment of the distinction between symptomatic tachycardia and tachycardia of specific origin is important. Upon this differentiation must often depend the recognition of auricular flutter after operation, and it may dispel the fear of infection as the cause of rapid heart and thus avert unwise surgical interference.

Herpes Zoster and Internal Disease—J Severin calls attention to the large number of cases of this association which are upon record. The report by Bittorf in 1911 of a case of zoster which appeared in connection with an attack of renal colic was followed by a swarm of similar reports in which every possible disease of the kidney, kidney pelvis, and ureter was present. Another group of zoster cases was associated with painful affections of the heart and aorta and a third group with the affections of the alimentary system. It was remarked incidentally that in practically every case the location of the eruption accorded with the particular Head zone which was associated with the diseased organ, while in the great majority of cases the organ affection was naturally a painful one. The author himself has seen no less than four cases of this association which he relates in full. The first two developed in patients with intermittent hydro-nephrosis in which renal colic was the eliciting cause. The third case occurred in association with an attack of hepatic colic in a patient with cholelithiasis, while the fourth patient suffered from angina pectoris itself due to sclerosis of the aorta. It is obvious that when a practitioner is confronted with a case of zoster he should locate the organ involved in the Head's zone of the eruption and examine the patient with especial reference to internal disease with painful manifestations, the source of which is easily confused in ordinary diagnosis. Scars of past zoster might have a similar diagnostic value.—*Deutsche medizinische Wochenschrift*, May 21, 1926

Further Evidence Pointing to the Identity of the Viruses of Herpes Zoster and Varicella.—Erich Hoffman states that von Bokay as long ago as 1892 began to point out the possibility of some association of necessity between these two affections. Thus he had repeatedly seen children come down with chicken pox after association with a patient with zoster. In 1923 the same pediatricist announced that he then had notes of more than 200 cases of this type, comprising a few in which a reversible action was present, the zoster appearing after association with a patient with varicella. He also pointed out that children who have gone through zoster are immunized against varicella. Recent serological tests also point to identity of the two viruses, the distinction between the two diseases being that while varicella is a blood stream infection zoster represents a lymph-stream propagation originating in the olfactory region and eventually reaching the posterior spinal nerve roots and their ganglia. It is certain that zoster virus has a peculiar neurotropism which is not much in evidence in varicella. We next arrive at the problem of double infection which in theory should be common, but the author could find only 22 cases in the older literature, the rule being that zoster appears first and is quickly followed by an outbreak of varicella. However, the symbiosis must be much more common than these small figures imply, for the author himself has seen two cases, and it is easy to see how others could be masked under such clinical diagnoses as generalized zoster and atypical varicella.—*Deutsche medizinische Wochenschrift*, May 21, 1926

Progressive Roentgen Ulcer Healed by Diphtheria Antitoxin—Professor F. Franke relates an interesting personal experience in the *Medizinische Klinik* of May 21, 1926. He had been a roentgenologist for 24 years without having developed any untoward professional symptoms, but two years ago he began to notice nutritive alterations in the finger ends, including a tendency to form ulcerations of a torpid character, very slow to heal. Recently he met with an accident when the left medius was caught in a slamming door, nearly losing the last phalanx. As the writer was a pianist he made an extra effort to save this member, although gangrene seemed almost inevitable, and succeeded in restoring circulation in the distal portion of the finger, but the vitality had been so reduced by the roentgen rays that ulceration set in and continued to spread, refusing to respond to any plan of treatment. It produced exuberant granulations and was very painful, and the loss of the member was again threatened. Although the author feared that a malignant roentgen ulcer might already have developed he resolved to persist with the con-

servative treatment. Recalling an army experience in which similar ulcers had been found to harbor diphtheria bacilli and which responded to diphtheria antitoxin, he determined to test the antitoxin although bacteriological examinations had shown nothing more virulent than the white staphylococcus, and applied dressings of 400 units each. To his intense surprise and pleasure the ulcer began to heal and slowly closed up. In explanation Franke had only one guess—that the horse serum in the antitoxin exerted the therapeutic effect. A slightly similar case is reported in which an ulcer of the same type was cured by a dressing of the patient's own blood.

A Study in the Disinfection of the Hands—Howard Lillienthal and Jerome M. Ziegler (*Annals of Surgery*, June, 1926, LXXXIII, 6) report tests on the mechanical cleansing of the hands by covering them with an easily visible substance and scrubbing until all traces of it has disappeared. A mixture of lampblack and oil and black machine grease from an automobile were selected as materials suitable for this purpose. It was found that microorganisms would not grow in lampblack and cottonseed oil, although the material is not truly bactericidal. For removing these materials certain commercial cleansing pastes were found to be superior to green soap. It was, however, impossible to remove all the foreign matter from beneath the finger-nails, hence for them a surer method must be employed. A procedure that proved so convincing that for about ten years many of those associated with Dr. Lillienthal have been employing it consists in the following steps: (1) The finger tips are immersed in tincture of iodine, and are immediately removed, the tincture being permitted to dry for five minutes. (2) While this is going on the remainder of the hands, including the wrists, should be painted with lampblack mixture up to the limits of the iodine. (3) The hands are washed by rubbing with the cleanser (a soap containing 85 per cent water, a small amount of free alkali, and various volatile oils) without water for about one-half minute. (4) The hands are then rinsed under hot running water. (5) They are then scrubbed with the cleanser and brushed until all traces of the lampblack have disappeared, scrubbing the arms as usual at the same time. (6) The alcohol scrub is employed in the usual fashion. It will then be found that most of the iodine discoloration has disappeared. The hands may now be dried with a sterile towel and the gloves put on. The use of the lampblack is not necessary as a routine, but it is most important as a training for those who wish to perfect themselves in operating-room technique.

THE DAILY PRESS

THE ORIGIN OF MAN

The subjects of evolution and the origin of man are frequently mentioned in the daily press. The New York Herald-Tribune of July 22nd contains a report of a lecture by Dr. H. Gideon Wells in Columbia University in which he is quoted as saying that the immunological reactions of the blood of the chimpanzee and orang-utan compared with that of man show that the tailless apes are related to man more closely than to the tailed monkeys.

Those who are interested in the evidences of the characteristics of early man will find interesting reading in the May-June number of "Natural History," the publication of the American Museum of Natural History, New York City, on page 271. Drs. Gregory and McGregor, of the staff of Columbia University say:

"After many years of intensive investigation of the subject from various angles, the present writers can state as a fact that by every criterion used to estimate zoological relationships, including the data of anatomy, embryology, physiology and pathology, the chimpanzee and the gorilla stand closer to man than to any tailed monkey."

The authors state, "The earliest known races of mankind were already true Hominidae and therefore, in spite of certain ape-like features, they hardly deserved the name of 'ape men'." It is generally recognized that each of the

modern anthropoid apes is specialized in certain peculiarities that definitely rule it out of the line of human ancestry. The known facts of palaeontology also prove that these two families must have begun to diverge from each other at some period before the Lower Pleistocene, and the human family probably did have a line of ancestry of its own which stretched backward far into Tertiary times. It would also be convenient to call these Tertiary men 'Dawn Men' if it be understood that *Eoanthropus* (Piltdown), the one that was originally so named, was one of the latest of the series."

There is much nonsense printed and spoken about man's descent from the monkey. The issue of *Natural History* that is quoted is entirely devoted to past races of man. It contains a summary of the evidence on which the theory of the evolution of the human race is founded. There are descriptions of the primitive Neanderthal man, of casts of the brain cases of fossil skulls, and of the characteristics of ancient teeth, and accounts of how the very old human remains were found, including pictures of the sites on which they were excavated.

The popular fear that study of evolution leads to irreligion is refuted by the fact that the first article in the magazine is by a Catholic priest, who is an authority on the ancient races that drew pictures in the caves of France and Spain some 25,000 years ago.

PERSONAL TRANSPORTATION IN NEW YORK CITY

The problem of traveling to and from work has so great effect on health that the Commissioner of Health is working on a plan called "The Stagger System." This is that the stores, offices, and theatres shall open at different hours so that the peak of travel which is now confined to an hour in the morning and another in the late afternoon shall be spread over two hours during each period. The New York Times of May 27 says that the Commissioner has already called conferences of business men who employ large numbers of workers, and has begun a survey of the number of workmen in New York City and their methods of going to and from work. The success of the Stagger plan will depend on the degree of cooperation that can be secured among both employers and employees.

The people of New York City are patient,

long suffering, and considerate of others. They are compelled to have these qualities, else life would be unbearable. In no other way could the great crowds which fill the station platforms and the cars travel in safety. The people of New York City will adapt themselves to congestion and crowding as long as they can, but when the limit of the number of cars that can run is reached, as it now is in rush hours, no amount of patience and cooperation can speed up transportation. The people will welcome The Stagger System of transportation when conditions compel them to.

Another solution of the transportation problem is that of zoning the city and assigning definite sections to business, others to trade, and others for residence. This plan is discussed editorially in the New York Times of May 27. It will require years for its adop-

tion, and is dependent largely upon the development of bridges, underwater tunnels, and the means of distributing freight in the city.

Another solution of transportation is that of establishing manufacturing centers in rural districts. Henry Ford is a practical advocate of this plan, and the Village of Hershey has sprung up around the plant of the chocolate manufacturer in Pennsylvania, and Endicott, N. Y., around a shoe manufacturing establishment near Binghamton.

The unknown quantity in making an intelligent plan for transportation is the individualistic manufacturer who thinks only of the immediate needs of his own business. New York City is a great aggregation of individuals, but the time is rapidly approaching when there must be either a high degree of cooperation, or the city must cease to grow and its people must spread to smaller towns where they may ride to work in their own automobiles.

HEALTH IN ART SUBJECTS

The New York Sun, February 20th, contains an editorial entitled "Health on Canvas" which is a discussion of health as shown by the human figures painted by the famous artists. The Editor says:

"It was the painter Sandro Botticelli who imposed on the world the test of slinness as a mark of beauty, in later years Rubens, whom Henry James called the painter of rosy brawn, may have tried to lead the world to look with a kinder eye on his robust type of pulchritude. Yet today it is the Botticelli type which prevails where Western ideals are in the ascendant. Slinness is essential to the beauty of these women. The privations they endure that the too solid flesh may disappear are evidences of the esteem in which they hold the leanness they so valiantly struggle to possess. One well known theatre manager in New York who engages hundreds of women every year for his enterprises says that 130 pounds is the top-most limit of the avoirdupois of any woman who expects to be on his beauty roll."

"It was years before the world discovered how it came about that Botticelli's ideal was slinness. The original of "The Birth of Venus" and "Spring" escaped emaciation but she was undeniably slender. It was not until the knowledge that she suffered from tuberculosis became widespread that Botticelli's ideal of beauty was seen to be one which could never have existed in a healthy subject. In spite of this model's lack of health the impression that slinness is an essential of physical beauty has prevailed down to this time and artists have never hesitated to declare themselves as on the side of Botticelli rather than Rubens. The cult of emaciation was never stronger than it is to-day."

The editorial discusses the adenoid faces of royal subjects painted by Sargent, and compares them with the absence of the adenoids in the paintings of Holbein.

Gouty too was shown in some famous portraits. The editorial says:

"Although Sargent may have interpreted

relentlessly some of his subjects—among them even the London art dealer Wertheimer—he never went so far as to declare that he was realist enough to reveal by their looks as he depicted them the dietary of his subjects. Such fame was thrust on him by the King's dentist, who evidently remained indifferent to the fact that the Sargent subjects were of the kind that got the most expensive food procurable, regardless of whether it was sufficiently supplied with vitamin B."

"It is not surprising that the symptoms of goiter should be noticeable in a portrait if any painter happened to possess such an unhealthful ambition as to send his subject down to posterity with the evidence of such physical imperfection. In a collection of ten Madonnas by famous masters a Dutch physician has called attention to the artist's unmistakable depiction of thyroidal enlargement."

"This physical peculiarity appears in so many portraits that the physician is able to demonstrate, at least to his own satisfaction, that the frequency of this disturbance in that day shows the prevalence of goiter at present is not due to any conditions that have come into existence of late. The burden of suspicion under which too thoroughly purified salt had labored seems to be materially lightened. So the investigator has at least some medical conclusions to excuse his inquiries into the mixed field of art and health, even if his work does not exonerate the painters for immortalizing goiter in their works of genius. There ought to be a limit even to medieval realism."

One may wonder why physical defects were included in portraits, even when the pictures were intended to be life-like. It has always been considered proper to conceal physical defects, and yet portraits of kings and queens often show them. The adenoid face of Queen Victoria could not be kept from a painting, but a goiter need not be revealed. The deformed waists of a few generations ago and the compressed feet of the present day support the theory that the defects shown in paintings were included intentionally as a part of a fad or fashion of the day.

BOOK REVIEWS

EXPERIMENTAL INVESTIGATIONS INTO THE EMOTIONAL LIFE OF THE CHILD COMPARED WITH THAT OF THE ADULT By HELGA E. G. Translated by GEORGE H. MORRISON, M.B. (Edin.) Octavo of 243 pages, with 9 plates. London, Humphrey Milford, New York Oxford University Press, 1925 Cloth, \$6.50 (Oxford Medical Publications)

This work is a highly scientific and painstaking study and observations on child emotions

Using instruments of precision the author sets out to investigate the effects of mental concentration, excitement, depression, etc., on the physiologic behavior of the subject under observation.

Plethysmographic tracings of the pulse wave, volume as well as respiration rate are made use of as indicators

The book should prove of great value to the one interested in child psychology

The author comes to the conclusion that the physiologic behavior of the child depends largely on its psychologic background. An important factor in the study of child training

HARRY AFFEL

THE BOOK OF PRESCRIPTION, WITH NOTES ON THE PHARMACOLOGY AND THERAPEUTICS OF THE MORE IMPORTANT DRUGS AND AN INDEX OF DISEASE AND REMEDIES By E. W. LUCAS, C.B.E., Fellow of the Institute of Chemistry, Fellow of the Chemical Society, and H. B. STEVENS, O.E.B., Fellow of the Institute of Chemistry, Eleventh edition. P. Blakiston's Son & Company, Philadelphia, 1926

This little volume of 350 pages is the eleventh edition of a collection of English prescriptions and serves to inform us of the Britisher's method of applying his therapy. The first edition came out in 1856 and the fact that it has gone through ten revisions indicates it is an English standard

With our present knowledge of pharmacology, it is difficult to understand the demand for any book of prescriptions, but that there is a demand is evidenced by the continued issuance of a book of this sort. Certainly this little volume is one of the best of its kind. Many formulae for "Colloidal" metal preparations are given, and in this particular it is ahead of our own publications of like title. For those needing suggestions in the detail of prescription formulation this should prove a useful book

M. F. DEL.

A HISTORY OF THE MASSACHUSETTS MEDICAL SOCIETY WITH BRIEF BIOGRAPHIES OF THE FOUNDERS AND CHIEF OFFICERS By WALTER L. BURRAGE, A.M. M.D. Secretary of the Society. Illustrated with views of some of the meeting places, reproductions of old documents and portraits of important officers. Privately Printed, 1923

This is a history of "the oldest State Medical Society in the U. S., with a continuous existence" of 141 years having been founded in 1781. While primarily intended for the profession of Massachusetts it contains matter of wider value, even to notes on the history of the Medical Society of New Jersey. It thus becomes one of the basic sources of medical history in this country. Yet it carries much that has perennial interest and present-day importance—witness sections on malpractice defence police duty and discipline (euphemism for ethics) the Library district medical societies indemnity insurance etc.

The activities are taken up by 10 to 50 year periods. Less attention is devoted to the scientific record (chiefly

by titles), than to professional life in its public and official relations. It is evident that medical politics plays its part even in the M. M. S. Many biographic sketches are given, including excellent portraits of some twenty of the subjects.

The book is issued in fine form, and constitutes a type-record of that organization's past and present, such as should be published by every self-respecting medical society that has reached an age of maturity

W. B.

PRESCRIPTION NOTES By ARTHUR L. TATUM. 16mo of 22 pages, with blank pages for selected prescriptions. Chicago, University of Chicago Press, 1925 Cloth, \$1.25

The first fifteen pages of this little book of twenty-two pages of text attempt to give the essentials in grammatical construction of prescription writing. Though very brief, there are many facts brought forth that are helpful, but on the whole, it is too incomplete to be of any great value to one desiring to become familiar with the art. In addition, there are seven more pages devoted to the more or less important preparations of the United States Pharmacopoeia, Tenth Revision. The balance of the book is made up of blank pages for selected prescriptions

FREDERICK SCHROEDER

EARS AND THE MAM-STUDIES IN SOCIAL WORK FOR THE DEAFENED By ANNETTA W. PECK, ESTELLE E. SAMUELSON and ANN LERMAN with an introduction by WENDELL C. PHILLIPS, M.D., President-Elect of the American Medical Association. F. A. Davis Company, Philadelphia, 1926. Price, \$2.00 net.

This book is a plea for better social service among the Hard of Hearing, especially those beyond the help of Therapeutics

The authors show a keen knowledge of the various types of deafness and strongly urge more careful co-operation between the medical man, especially the Otolologist, and those socially interested in the deafened

Various methods of social adjustments are recommended. Of these lip reading is the most important in the opinion of the authors

Though strictly a social work every otologist as well as general practitioners should read it.

S. H. DEC.

THE COMMUNICABLE DISEASES. How They Spread and How They May Be Controlled. By ALLAN J. McLAUGHLIN, M.D. Octavo of 269 pages. New York and London, Harper and Brothers, 1923. Cloth, \$2.50 (Harper's Public Health Series.)

This is one of a series of books on public health topics edited by Dr. McLaughlin. It is written especially for the more intelligent portion of the laity who are interested in and capable of understanding a non-technical discussion of these diseases

Part 1 is introductory, giving a brief account of bacteriology, epidemiology carriers and methods of infection. Part 2 deals with diseases spread by discharges from the respiratory tract. Part 3 with disease of intestinal origin. Parts 4 and 5 with diseases transmitted by insects and animals and Part 6 with venereal and other diseases

The style is clear and simple and there is a minimum of technical language. The author shows his tropical training and his descriptive powers in the short yet vivid description of a cholera post-mortem. This book is well worth reading

E. B. SMITH

RATS AND HOW TO DESTROY THEM By MARK HOVELL, F.R.C.S., with introduction by S L BENSUSAN William Wood & Co, New York, 1924 Price, \$5.00

This book is a very complete work on the destruction of one of the worst pests known to civilization. It not only makes one realize the terrific monetary cost to which man is put when they are present, but it also emphasizes the fact that they are disease breeders and carriers

The chapters on the elimination of the rodent are very comprehensive and complete. They are absolutely vital to those who are interested in this phase of work.

The book is an asset to the commercial man as well as the sanitarian or public health expert.

J J W

LIVING ORGANISMS An Account of Their Origin and Evolution By EDWIN S GOODRICH, F.R.S. 12mo of 200 pages with illustrations London, Clarendon Press, New York, Oxford University Press, 1924 Cloth, \$2.00

An extremely interesting little book of 200 pages, including a bibliography and index, which deals "with modern views on the nature of life and the relation of living organisms to their environment, and with the latest advances in our knowledge of Heredity and kindred problems." It is a good introduction to the study of organic evolution, available for both scientific student and general reader. There are nine chapters devoted to: I. Nature and Origin of Life, II, Cellular Structure of Organisms, Reproduction, Death, III, Darwinism and Heredity, IV Variation and Factors of Heredity—Determination of Sex, V, the Struggle for Existence and Natural Selection, VI, Isolation and Sexual Selection, VII, Phylogeny and Classification, VIII, Geological record of success and failure, IX, Psychology and Evolution of Intelligence. There are sixty illustrations. The style is very clear and the subject matter, arranged as it is by one eminent in the fields of zoology and comparative anatomy, reflects the views of the great masters who have, in the past and present, devoted their lives to the study of life on this earth. We recommend this book as filling a very important need for busy people who feel the necessity of having some grasp on a subject of first importance to those whose duty it is to stand sponsor for the health of the community

J M VAN COTT

A SYNOPSIS OF SURGERY Illustrated. By ERNEST W HEY, GROVES, M.S., M.D., B.Sc. (Lond.), F.R.C.S. (Eng.) Seventh Edition William Wood & Co, New York, 1925 Price, \$5.00

A very concise presentation of the subject is offered in this volume. Particular stress is laid on the important symptoms and diagnostic signs of surgical diseases, whereas treatment is very briefly considered.

It should be particularly valuable to the general practitioner as an aid in differential diagnosis because the text is so arranged that reference to the salient features of each disease can be readily made.

HARRY KOSTER

THE RADIOLOGICAL EXAMINATION OF THE MALE URETHRA By G L S KOHNSTAM M.R.C.S. (Eng.), L.R.C.P. (Lond.) Preface by SIR JOHN THOMSON-WALKER OBE M.B., F.R.C.S. William Wood & Co, New York, 1925 Price, \$5.50

This small volume is a most interesting presentation of one of the more recent developments in the diagnosis of pathological lesions in the male urethra and bladder neck. It is very well illustrated and should be carefully studied by everyone who is interested in diseases of the urinary organs in the male.

N P R.

THE NORMAL DIET A Simple Statement of the Fundamental Principles of Diet for the Mutual Use of Physicians and Patients By W D SANBURN, M.S., M.D., Director Potter Metabolic Clinic, Santa Barbara Cottage Hospital. Illustrated The C. V Mosby Co, St Louis, Mo., 1925 Price, \$1.50

In this little book we at least can read about something normal. It is very instructive and brings out some things in diets that we are sure are not generally known.

It can be read in less than an hour and will save one many day's time when subsequently writing out a diet.

KENNETH MAC INNES

PERSONAL AND COMMUNITY HEALTH By CLAIRE ELSNIERE TURNER, Associate Professor Biology and Public Health, Mass Institute Technology. Illustrated. The C. V Mosby Co, St Louis, 1925 Price, \$2.50

This book, written as a text for students, is admirably suited for the purpose, although it is too elementary to be used as a text in the medical college. For the individual it offers excellent advice in personal hygiene. One feature which will be found especially valuable to the student who wishes to go more deeply into the subject of public health generally or into some particular phase of the subject is the extensive bibliography which the author furnishes at the end of the book.

E H. M

THE MEDICAL ASPECTS OF CHEMICAL WARFARE. By EDWARD B VEDDER Lieut. Colonel, M.C., U.S.A. With a chapter on the Naval Medical Aspects of Chemical Warfare, by DUNCAN C WALTON, Lieut. Commander, M.C., U.S.N. Octavo of 327 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$6.50

The reviewer must admit he did not read this book through. He would have liked to have read it but his ignorance of several technical phases of the subject prevented him from continuing. But what he did read more than repaid him for the time consumed. He is sure that to one who is interested in this subject and understands physics as applied to chemical warfare, elementary chemistry of Chemical Warfare, meteorology and the characteristics of smoke and gas clouds, will find the whole book one of fascinating interest.

Every physician who is a war veteran will read this book with understanding and pleasure

The illustrations are good. Particularly the reviewer would say a word about the book from a typographical standpoint it is perfect.

T W

VISUAL FIELD STUDIES By RALPH I LLOYD M.D., F.A.C.S. Octavo of 216 pages with 124 illustrations New York, The Technical Press, 1926 (For sale by E. C Swezey, 50 Pine Street, New York City) Cloth, \$6.00

We have received a great deal of pleasure and profit in reading Dr Lloyd's book. It is well printed and bound, and the illustrations are excellent and to the point.

In the first chapter, he has given a history of perimetry. The next chapter is devoted to the physiology of the retina and the practical application to field examination.

In the third part is taken up the subject of normal fields and blind spot with a description of the instruments used from the first and simple device of Von Graefe to the improved ones of today, and a description of the technique to be used in making visual field measurements.

According to the author any case in which there is a vision with correction of less than 20-20 for which no explanation can be found in the various media, is a fit case for visual field study.

Next is taken up in order, the effect of Chorio-Retinal diseased conditions, Retro-Bulbar Disease, Chiasm Disease, Tract Disease and lesions behind the Thalamus and in the Cortex.

We have here then in this book a comprehensive presentation of the subject in a form most accessible.

CHARLES A. HARGITT

THE EFFECTS OF IONS IN COLLOIDAL SYSTEMS By Dr LEONOR MICHAELIS 12mo of 108 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$2 50

The monograph is made up of the material presented by the author in a series of lectures in this country. A resume of the changes produced in colloidal systems by various types of ions is given and the results of such action interpreted in terms of absorption phenomena. Donnan's theory of membrane equilibria is mentioned briefly. The application of these physico-chemical changes in colloidal solutions to biology is always kept in view. The book is not too technical for the general reader interested in the fundamental facts of living processes.

A. GOERNER.

SIMPLIFIED NURSING. By FLORENCE DAKIN R.N. Octavo of 499 pages, illustrated Philadelphia and London, J. B. Lippincott Company, 1925 Cloth, \$3 00

The object of this book is to present the principles and the practice of nursing in a way that they may be made available to the members of a family who are caring for a patient, to a practical nurse, or to a trained attendant.

The matter is presented in the form of lessons, which follow the general plan of definition, explanation and instruction, with caution, safe-guard and note, where needed. The arrangement of lessons is well adapted for the use of High School classes in Nursing.

The last part of the book is devoted to Special Nursing, and includes a discussion of bacteriology, communicable diseases and emergencies. There is a very serviceable Supplementary Reading List, Glossary and Subject Index.

This book serves a useful purpose. It is simple enough to be understandable by and therefore available to, the home nurse and the practical nurse, and, at the same time, it is sufficiently inclusive and accurate to satisfy the demand for thoroughness and accuracy in nursing instruction.

J. R.

MODERN MEDICINE. Its Theory and Practice in Original Contributions by American and Foreign Authors. Edited by SIR WILLIAM OSLER, Bart., M.D., F.R.S. Third Edition, thoroughly revised. Re-edited by THOMAS McCRAE, M.D., assisted by ELMER H. FUNK, M.D. Volume 1 Octavo of 845 pages, with illustrations. Volume 2 Octavo of 891 pages, illustrated. Volume 3 Octavo of 1052 pages, with illustrations. Philadelphia and New York, Lea and Febiger, 1925-26. Cloth \$9 00 per volume.

Medical books grow old and are forgotten, except for those who like to look back at the milestones in the progress of science, or else they are revised and come to us again with a maturity and strength seldom seen in a first edition. What is true and fine in the youth of the book is preserved and with the better perspective of a new day the subject can be traced and illuminated with more precision and with the advantage of a knowledge of the newer discoveries. So Osler's Modern Medicine is reborn.

In the twelve years that have elapsed since the appearance of the Second Edition much of importance has developed. The revision represents a tremendous amount of work which is more than justified in the re-

sult. A critical review of so many exhaustive articles is hardly possible. The names of the contributors carry much weight, but were each section anonymous, the completeness and skill of presentation would be commendation enough.

Volume 1 covers bacterial diseases and the mycoses. Volume 2 includes diseases of unknown etiology, protozoan and spirochetal infections, diseases caused by animal parasites, diseases due to physical agents, chemical and organic agents and deficiency diseases. The third volume is given over to diseases of metabolism and diseases of the digestive system.

These volumes furnish a review of modern medical knowledge such as should be in the library of every practicing physician.

T. H.

BUCHANAN'S TEXT-BOOK OF FORENSIC MEDICINE AND TOXICOLOGY By JOHN E. W. MACFALL, M.D., D.P.H., M.B. Ch.B. Pa.C. Octavo of 445 pages, with illustrations. Ninth Edition, revised and enlarged. New York, William Wood and Company, 1925 Cloth, \$5 00

This little work in parts is as good a treatise as has been written on this subject. The mode of legal procedure is purely English and not adapted to our methods. The post-mortem examination and identification of the mode of death is as fine an article as exists. The chapters on rape, pregnancy, infanticide are less clear and useful. That on inheritance, legitimacy, impotence and sterility, malpractice, neglect of duty, feigned diseases and wills will not be found of much use to doctors outside the British Isles. The chapter on mental unsoundness is the weakest part of the book as the psychiatry is that of fifty years ago and a modern physician would find it hard to identify some of the classifications which is based on British Judicial opinion and not on medical.

A. C. BRUSH

THE HISTOLOGY OF THE MORE IMPORTANT HUMAN ENDOCRINE ORGANS AT VARIOUS AGES By EUGENIA R. A. COOPER, M.D. Octavo of 119 pages, with illustrations. London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$4 00 (Oxford Medical Publications)

This book is based upon the findings of a study of the endocrine glands obtained by autopsy. While some glands pass through various stages depending upon the age of the individual, others maintain a normal degree of activity through life. The thymus and the thyroid show changes incidental to age, while the parathyroids do not.

The description of the structural changes observed in the glands are detailed and should prove of great value to others for comparative purposes. The book should prove to be very helpful to all interested in the subject.

M. B. GORDON

HANDBOOK OF PATHOLOGY By C. Y. WANG M.D., Edin., B.Sc., Vict., F.R.C.P., Edin. with two hundred and eighty-two illustrations. William Wood and Co., New York, 1925 Price, \$7 00

This work is written with the especial purpose of presenting, particularly to medical students, a pathology which is concise as well as comprehensive. It is given over to the more important pathological conditions, paying particular attention to the etiology and morbid anatomy.

The author has inserted plates which add greatly to the attractiveness of the volume and well illustrate the salient points of the microscopic pathology. The book may be in no way considered as replacing a general pathology, the author's aim in this edition is devoted to the fundamentals without discursive detail.

R. E. CAMPBELL

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

EMERGENCY SURGERY The Military Surgery of the World War Adapted to Civil Life. By GEORGE DE TARNOWSKY, M.D., F.A.C.S., D.S.M. Octavo of 718 pages, with 324 illustrations Philadelphia and New York, Lea and Febiger, 1926 Cloth, \$7 50

THE CLINICAL INTERPRETATION OF THE WASSERMANN REACTION By ROBERT A. KILDUFFE, A.B., A.M., M.D. Octavo of 203 pages, with illustrations Philadelphia and New York, Lea and Febiger, 1926 Cloth, \$2 50

THE EARLY RECOGNITION OF THE VARIOUS TYPES OF SYPHILIS *

(A DIAGNOSTIC STUDY OF ONE HUNDRED AND FIFTY CONSECUTIVE CASES, TOGETHER WITH THE DESCRIPTION OF A NEW ORAL SIGN OF THE DISEASE)

By ALBERT CRANCE, M D, GENEVA, NEW YORK.

GENERALLY speaking, we are all fairly familiar with the course that syphilis takes while invading the human body, chiefly, that it starts with a chancre and goes on into a secondary stage with its characteristic rash, sore throat and occasionally alopecia, and later into the third stage which may include pathology in any part or parts of the body. The typical textbook picture of the disease has been dwelled upon so much that the obscure types or atypical cases are frequently overlooked.

The principal purpose of this paper is to emphasize a few of the more uncommon points in the diagnosis of the disease but which, relatively speaking, are equally as important if they arrive at a final diagnosis of the disease. It matters not necessarily, how one arrives at the final diagnosis if one has been able in his efforts to diagnose the presence of syphilis because the ultimate purpose of diagnosis in any lesion is to guide us in the proper treatment. The patient with obscure syphilis, who has been "the rounds" without definite diagnosis, wants to be told what his trouble is, and, when once the case is diagnosed he is invariably benefited by specific treatment. In practically all medical and surgical diseases, syphilis is to be considered. It may be masking itself in one way or other, trying to puzzle the physician, because the disease, as Osler has stated, may mimic all other diseases. This statement applies to all three stages of the disease, but perhaps it applies to better advantage in the later stages.

After reviewing a fairly large series of carefully studied cases, there are certain definite conclusions to be drawn therefrom. In the first stage of the disease, that is the primary lesion or chancre, the lesion is frequently mistaken for something else. The diagnosis of this lesion cannot always by any means be made clinically. Here, our laboratory findings are very essential. The spirocheta pallida, when demonstrated in the

serum from the lesion, is conclusive. At this point it must also be emphasized that the blood Wassermann test will invariably be negative and consequently, is of no value in diagnosing the primary lesion of syphilis from other conditions. And yet we find that a certain number of cases have had Wassermanns taken in this first or early stage which were negative and have gone elsewhere to have a laboratory diagnosis made even before the secondary symptoms appear.

It must also be remembered that the primary lesion of the disease may occur on any part of the body and does not necessarily limit itself to the genitals or to the lips or tongue. The writer has, in fact, seen one case in which the primary lesion was on the back of the hand, indeed a most remote location.

History—Considerable stress is made in textbooks regarding the time of appearance of primary lesions, namely that they occur fourteen to twenty-eight days following exposure. Occasionally, this is of some value but in the majority of cases, if we are convinced at all by the history, we are likely to arrive at wrong conclusions. The majority of histories in these cases are of no value. Histories in the later stages of the disease are still less valuable. The majority of cases of neuro-syphilis or other obscure types, when told what they have, will deny that any primary lesion ever existed. A great many of these cases, however, will admit a previous gonorrheal infection, perhaps ten or thirty years prior. So often is this coincidence that it seems logical to believe that many cases of gonorrheal infection are accompanied with chancre either in the urethra or, as is often found, a small lesion tucked away under the frenum. In women, the history cannot at all be relied upon for the main reason that the majority of women have no visible signs of the disease until the secondary stage. A large percentage of chancres occur on the cervix or in the vaginal orifice and are consequently not visible. Therefore, in the majority of cases, it is logical to discount any value from the history.

* Presented at a meeting of the Penn Yan Hospital Staff, March 16, 1926, and before the Geneva Clinical Club, March 8, 1926.

FIG 1—Illustration showing the triangular or fan-shaped whitish thickening as it occurs in the mucous membrane at the angles of the mouth in latent syphilis. In this particular case the only additional sign was a mild tubercular syphilis on the forearm as shown in Fig 2. The Wassermann was 4 plus. The condition is usually bilateral.

In the secondary stage, the differential diagnosis becomes mostly a matter of dermatology. The character of the rash, which is maculo-papular in type, has a characteristic appearance but unaccompanied by symptoms. It usually starts on the abdomen, chest or back and thence to the arms or thighs. The most characteristic word the writer can use in describing it is that it appears as a reflection, or it might be described as appearing under the skin. The sore throat which accompanies this stage may vary considerably in detail. In fact, it may not even be present. It may vary from a slightly reddish inflamed throat to severe ulceration in the region of the tonsillar pillars or the uvula. The alopecia, when present, is usually of the "moth-eaten" appearance with ragged edges.

The third stage is indeed a separate chapter in the study of medicine. We are all aware that syphilis *may* hide itself, but as a matter of fact, it *does* hide itself, and for that reason the points which are made most of in this paper are those relative to the later stages or obscure types of the disease. There is much to be learned regarding the pathology of this third stage as to just what occurs in various parts of the body. However,

such workers as Warthin, Stokes and others have conclusively proven that the spirochete remains active in such organs as the spleen and liver and they have even been demonstrated in the heart muscle. For simplifying the third stage, it is perhaps easiest to classify under three separate headings, namely Dermatological, internal and neuro-syphilis. Gumma may of course, involve either.

The Complaint—These patients of course, may complain of a long list of ailments, depending upon the particular part of the body affected with the disease. Most of these complaints do not suggest the disease, except one in particular which is principally a group of complaints regarding general weakness, with noticeable loss of strength in the legs perhaps associated with some stomach distress and at times some frequency of urination. This chain of complaints may often be associated with an early involvement of the spinal cord.

A New Oral Sign of Late Syphilis—The writer has made a fairly extensive study of the literature dealing with oral signs of the disease and has been unable to find any description of the following condition which consists chiefly of a triangular or fan-shaped thickened area of leukoplakia in the mucous membrane at the angles of the mouth. In the accompanying photograph (Fig 1) it will be noticed that this sign is clearly illustrated. In this particular case the only additional sign was a tertiary tubercular syphilide lesion on the forearms. The Wassermann was four plus. In this series of 150 cases, 21 presented this oral sign. During the course of the general examination it has become a routine procedure to examine this area. The condition is to be differentiated, however, from irritation due to projecting teeth or severe pyorrhea and also a true leukoplakia of the mouth.

FIG 2—Illustration of a tubercular syphilis lesion on the forearm. There were no other lesions on the body except at the angles of the mouth.

The Examination—One of the reasons perhaps, for stressing routine general examinations in large clinics, is to avoid missing some important finding which may indicate lues. It is

necessary during the course of the examination to look for certain features in practically every part of the body. If this series demonstrates anything at all, it does show the various objects to look for in making our general examinations and especially when we are interested in finding the existence of syphilis.

We are all quite familiar with the primary stage of the disease and yet errors are frequently made. Consequently, we cannot afford to let any venereal sore go along without a special examination for the *spirocheta pallida*. It is surprising, the number of such sores which have been diagnosed as non-specific in which the spirochetes can be demonstrated when the examination is made. Consequently, all such lesions should be examined, as clinical opinions amount to little or nothing at this stage of the disease.

ANALYSIS OF 150 CASES

Males	104 or 67.3%	Early	40
Females	46 or 30.6%	Types—Late	99
		Congenital	11
	150		150

The secondary stage which is also an early stage of the disease, is quite characteristic, however. Any person with a suspicious non-itching general skin rash should have a Wassermann, and also a careful search for the primary lesion, especially in the male. In this series three cases of intra-urethral primary lesions occurred and the diagnosis was not made until the secondary stage developed. It might be well to state here that skin lesions of syphilis occasionally itch, so an itching skin does not rule out the disease.

BLOOD WASSERMANN REACTIONS

Of the 150, 121 were positive, 29 were negative.

Of the 29 negatives, 21 were early *primary* lesions.

4 were also negative in spinal fluids.

4 were positive in spinal fluids.

Therefore, disregarding the 21 early cases with negative blood reactions, there were 121 positive reactions out of 129 in which positives might have been expected, or in other words, 93.7% positive blood reactions.

The blood reactions were as follows:

4 plus	109
3 plus	4
2 plus	4
1 plus	4
Negative	29
	150

Latent syphilis demands a more detailed examination. The pupils will perhaps show the disease more often than other parts of the body. They should always be examined for a difference in their sizes as well as their reaction to light. The Romberg test is often positive or suggestive, and should always be taken. The patellar reflexes should likewise always be taken. If they are exaggerated it may mean neuro-syphilis or if they

are diminished or absent it may mean neuro-syphilis. Compare the two sides. The writer has in several cases noticed that when the right pupil is dilated and the left patellar reflex exaggerated, that the Wassermann is usually positive. Neuritis is fairly frequent. The thighs and girdle region, also the shoulder and arm are frequently affected. One case in this series, a woman, went to seven physicians for a neuritis of her left shoulder and arm before she had a Wassermann taken and the diagnosis of syphilis made. Urinary frequency is more apt to be present when the spinal cord is involved. It is common in locomotor ataxia and frequently these patients are cystoscoped only to find a specific appearance which is termed by Braasch "cord bladder." Hoarseness of voice is also fairly prevalent and is not always due to colds or alcoholism. It is common in syphilis.

Gumma usually presents itself with some definite enlargement of the part or it may appear as a simple elevation beneath the skin, and later has a tendency to ulcerate. In this series, one case of gumma of the breast is reported in which a Wassermann was fortunately taken before the patient was submitted to operation. It closely resembled a tumor. Interstitial keratitis is more often found in the congenital type of the disease. Its picture is quite familiar to all. However, the condition may come on as late as the age of eighteen or twenty and is not to be confused with cases of foreign body in the eye, which of course, is valuable in compensation work. External strabismus may be slight or definitely noticeable. When one of the eyes is noted to be out of alignment laterally, we should keep in mind the possibility of syphilis. Large lower lips are very frequently a late manifestation of the disease. Stomach symptoms are not uncommonly due to the disease and very frequently the symptoms closely resemble those of gastric ulcer. The pain, however, is usually worse when walking. The writer believes that no case presenting indications for gastric surgery should be operated upon until syphilis has been ruled out. At least, the Wassermann should be a routine. The nose may be the only part affected with the disease at times. There may be thickening of the tissue in the nose and sometimes perforation of the septum. Externally it may show hypertrophy and extreme redness. The heart is frequently attacked by the disease. The aorta is a favorite site for the spirochetes to work and many times syphilis is not diagnosed until at the autopsy table a specific aortitis is found. Impotency is also fairly commonly associated with the disease. In this series, 7.2 per cent of the latent cases showed impotency. Alopecia is not very important except in the secondary stage of the disease. The hair, however, has its characteristic "moth-eaten" appearance. Speech impediment occurs frequently enough to be suspicious at

FIG 1—Illustration showing the triangular or fan-shaped whitish thickening as it occurs in the mucous membrane at the angles of the mouth in latent syphilis. In this particular case the only additional sign was a mild tubercular syphilis on the forearm as shown in Fig 2. The Wassermann was 4 plus. The condition is usually bilateral.

In the secondary stage, the differential diagnosis becomes mostly a matter of dermatology. The character of the rash, which is maculo-papular in type, has a characteristic appearance but unaccompanied by symptoms. It usually starts on the abdomen, chest or back and thence to the arms or thighs. The most characteristic word the writer can use in describing it is that it appears as a reflection, or it might be described as appearing under the skin. The sore throat which accompanies this stage may vary considerably in detail. In fact, it may not even be present. It may vary from a slightly reddish inflamed throat to severe ulceration in the region of the tonsillar pillars or the uvula. The alopecia, when present, is usually of the "moth-eaten" appearance with ragged edges.

The third stage is indeed a separate chapter in the study of medicine. We are all aware that syphilis *may* hide itself, but as a matter of fact, it *does* hide itself, and for that reason the points which are made most of in this paper are those relative to the later stages or obscure types of the disease. There is much to be learned regarding the pathology of this third stage as to just what occurs in various parts of the body. However,

such workers as Warthin, Stokes and others have conclusively proven that the spirochete remains active in such organs as the spleen and liver and they have even been demonstrated in the heart muscle. For simplifying the third stage, it is perhaps easiest to classify under three separate headings, namely Dermatological, internal and neuro-syphilis. Gumma may of course, involve either.

The Complaint—These patients of course, may complain of a long list of ailments, depending upon the particular part of the body affected with the disease. Most of these complaints do not suggest the disease, except one in particular which is principally a group of complaints regarding general weakness, with noticeable loss of strength in the legs perhaps associated with some stomach distress and at times some frequency of urination. This chain of complaints may often be associated with an early involvement of the spinal cord.

A New Oral Sign of Late Syphilis—The writer has made a fairly extensive study of the literature dealing with oral signs of the disease and has been unable to find any description of the following condition which consists chiefly of a triangular or fan-shaped thickened area of leukoplakia in the mucous membrane at the angles of the mouth. In the accompanying photograph (Fig 1) it will be noticed that this sign is clearly illustrated. In this particular case the only additional sign was a tertiary tubercular syphilide lesion on the forearm. The Wassermann was four plus. In this series of 150 cases, 21 presented this oral sign. During the course of the general examination it has become a routine procedure to examine this area. The condition is to be differentiated, however, from irritation due to projecting teeth or severe pyorrhea and also a true leukoplakia of the mouth.

FIG 2—Illustration of a tubercular syphilis lesion on the forearm. There were no other lesions on the body except at the angles of the mouth.

The Examination—One of the reasons perhaps, for stressing routine general examinations in large clinics, is to avoid missing some important finding which may indicate lues. It is

tion they have given and also to congratulate them on their painstaking technique.

Summary—In summarizing this series of one hundred and fifty cases one can easily see that the diagnosis of syphilis is not spelled with capital letters in any particular location. Its study demands a knowledge of the pathology of the entire body both externally and internally. Its diagnosis moreover, demands keen and careful observation. There is perhaps no class of cases which really appreciate a diagnosis more than the patients afflicted with some obscure lesion of the dis-

ease, for nearly all of them have made several attempts on previous occasions to find out why they are sick. When told that in most instances they can look forward to being greatly benefited, the encouragement is indeed greater to them than if we told them they had a cancer or pernicious tuberculosis. There is a specific treatment for syphilis and none for the other two mentioned. In conclusion therefore may it be emphasized once again that our examinations be more complete and directed somewhat more toward the things which are not spelled with capital letters.

BULLETS AS EVIDENCE IN SHOOTING CASES IMPORTANT CONSIDERATIONS RELATIVE TO THEIR REMOVAL AND PRESERVATION

By CALVIN H. GODDARD

ASSOCIATE DIRECTOR (LATE MAJOR MEDICAL CORPS U. S. A.) BUREAU OF FORENSIC BALLISTICS
NEW YORK CITY

IT is sad but true that many a man guilty of murder gains an acquittal, and an occasional innocent one meets conviction, through carelessness on the part of those responsible for the collection and preservation of articles of evidence. In shooting cases the important objects, aside from the clothing penetrated, include the weapon, bullet or bullets, and empty shell or shells. The arm ordinarily goes into the hands of the police as do the exploded shells, but the bullet not infrequently remains in the custody of the coroner, medical examiner, or other medical official, until produced in court, and since the projectile alone may tell a very complete, if silent, story, a few words as to its proper recovery and aftercare may not be amiss.

He who removes a bullet from a body at autopsy should be acquainted with certain important facts and keep them constantly in mind. He should know that the missile bears engraved upon its surface a "fingerprint,"—that of the particular arm through which it has passed, that this fingerprint will serve to identify that arm among all others existing today, just as accurately as his own fingerprint identifies him among all the inhabitants of the world, and that the majority of its important landmarks are considerably more delicate than those of a sweat-stained digit upon a piece of glass, almost as easily obliterated by careless handling, and, once obliterated, just as impossible of reconstruction.

Now if you were handed a fragment of glass bearing a fingerprint, evidence of a murder, would you drop it in your pocket, to grind about with the other objects therein, and forget it until the inquest was called, or would you put it carefully away in a properly labelled box until it could be studied adequately? The answer is obvious. And if you fail to do the same in the case of a bullet, under similar circumstances, you are guilty of gross and unpardonable negligence. Yet the

FIG. 1.—Matching the "finger marks" on two bullets placed end to end.

"pocket treatment" is all too often accorded to the recovered bullet, even today (and some pockets have been known to have holes in them) by men who should know better.

least when it is present. The rectal examination should always be made and anything from stricture to ulcerations or condylomata should arouse suspicion. One case of pain in the neck and ears occurred in this series which is of course, less than 1 per cent. It should perhaps be classified with neuritis but it is classed separately to illustrate how syphilis has no preference as to where it may attack the human body. Ptosis of the upper eyelid is more often specific than it is non-specific. Snuffles is a definite sign of congenital syphilis. Its presence in the infant should at least demand a Wassermann on the mother and father when it is not possible in the child. In fact, all cases of congenital syphilis demand careful study of the parents. The mother is always syphilitic, but the father does not necessarily have the disease. Deafness occurs in both the late types as well as occurring in the congenital cases. The disease causes an ossification of the ear drum. The skin is occasionally the site for late manifestations principally in the form of tubercular syphilide as well as ulcerating gummata. Lesions in the mouth take the form more often of white thickened areas and especial attention has been called previously in the paper to a new oral sign of the disease. Headaches occur fairly frequently. Eight cases of headaches in this series were due to syphilis. Paralysis of the limb, if unilateral, is more apt to occur in children with the congenital type of the disease, whereas, bilateral paralysis more often occurs in the latent acquired type following spinal cord involvement. The finger nails and toe nails are not to be forgotten. Specific onychia is to be considered in differentiating the various diseases of the nails. In the consideration of congenital syphilis we should keep in mind three definite signs known as Hutchinson's Triad. These are Interstitial Keratitis, Hutchinson Teeth and Ossification of the Tympanum. When these three findings occur in a child the diagnosis can be made without a Wassermann. It is a positive triad.

Blood and Spinal Fluid Wassermann—In this series of cases, it will be noticed that the Wassermann test was positive in over ninety-three per cent, in those on which a positive reaction could be expected. It will be further noticed that very few cases which did not show at least a one plus blood, showed a positive spinal fluid Wassermann. It would seem that too often the spinal fluid is a concluding factor. There is no question that spinal puncture is being done too much and too often at the discomfort of the patient. If we find sufficient cord involvement and other clinical data to establish our diagnosis, together with positive blood Wassermann, we can rest assured that the patient has lues of the central nervous system without taking a spinal fluid. In any event, the treatment should be instituted in the beginning towards the general side of the case rather than the

OCCURRENCE OF SPINAL FLUID REACTIONS IN THOSE WITH NEGATIVE BLOOD REACTIONS

Out of the 8 latent cases with negative blood reactions, 4, or 50 per cent, gave positive spinal fluids of which 2 were 4 plus, 2 were 2 plus

special neurological side. After the patient has had a general course of treatment, the spinal fluid should then be taken, and if positive, treatment should be directed according to the method of Swift and Ellis or by the procedure of spinal drainage (Allen). In this series there are cases which have had good improvement by generalized treatment alone and others in which the results were better when general and spinal treatments were combined. There can be no doubt as to the importance of intraspinal therapy and its use in proper cases is strongly advocated. However, it seems more logical to treat the general infection first and then later, if indicated, the intraspinal treatment. It might be well to mention that it is quite important to know one's laboratory and to get accustomed to interpreting their findings. In this series, the laboratory work has been done by the New York State Department of Health at Albany, New York, and as the summary shows, the percentage of accuracy checks up exceptionally well with the clinical data. The writer wishes to thank this laboratory for the splendid coopera-

Figure 2

FIG. 4—How to place identification marks on bullets removed from a body

times, following the same trough each time, and gradually deepening it) Where it has a microscopic projection the groove will register a corresponding depression, and vice versa. To the eye, the surface of the finished groove may appear as smooth as glass, but if sectioned transversely and its edge examined under moderate magnification the "wavy" character of its surface will at once become evident

Now bullets are softer than the barrels they traverse, else the latter would soon wear out. Hence the irregularities of the barrel's surface are impressed upon the bullet, rather than the opposite. The result is a series of fine straight lines or striae running along the cylindrical portion of the bullet (the portion in approximation with the bore surface) parallel to the deep cuts left by the edges of the grooves. After an arm has been in use for some time, these markings become decidedly more pronounced, for upon the original very slight irregularities in the surface of the bore are superimposed much more striking ones produced by pitting, rust accumulation, metal fouling, etc.

Furthermore, since each maker must allow more or less tolerance in the execution of the rifling process we find upon accurate measurement (to ten thousandths of an inch) that the width of any one groove (e.g., M-N of barrel A, Fig 2) does not by any means necessarily equal that of the next groove, (O-P) in the same barrel. It may be

several thousandths of an inch wider or narrower. And the same is true as to groove E-F of barrel B measured against the next groove (G-H) within that barrel. And there is of course no constant relationship between these ratios, from barrel to barrel. Thus, one is not necessarily equal to another but may be less or more. Since a bullet becomes, on being fired, virtually a cast of the bore through which it passes, we can, by measuring accurately the width of each land and groove mark left upon it, reconstruct the measurements (at the muzzle) of the several lands and grooves in the barrel that fired it. It should be evident that the manner in which these vary from groove to groove, and land to land, can hold for one individual arm, and only one. Thus we have a second finger print in every barrel for the land-groove measurements on all bullets projected by it will duplicate one another, and its own, exactly. A study of the actual dimensions of the lands and grooves in two barrels from arms of the same model by the same maker, as entered upon them in Fig 2 should demonstrate clearly that accurate measurements of the lands and grooves on 1 bullet fired from either would link it at once to the one from which it issued, and prove the impossibility of its being connected with the other.

But suppose a bullet is badly battered, as by striking bone? This may so destroy or distort the land-groove pattern as to render it useless for purposes of identification. It is rarely that all

FIG 2—Measurements of rifling grooves

(To promote simplicity, barrels shown above are drawn with but four grooves, while most American manufacturers employ five or six)

Why does the bullet deserve such tender care? Because the grooves and ridges impressed upon its surface by the rifling (and other markings) of the barrel through which it has passed, may be likened to the ridges on the finger tip. But while the finger's ridges number some scores, each approximately as prominent as every other, and disposed in a sinuous formation whose basic difference from any other is readily apparent on comparison, the prominent ridges on a bullet (those inscribed by the edges of the barrel's grooves) number but three to six *pairs*—rarely seven or eight. Further, instead of being curves they are

straight lines, arranged parallel to one another about the cylindrical portion of a bullet, equidistant, and at a slight angle to its axis. As they issue from different specimens of arms of the same make, caliber, and model, they appear *exactly* alike*. There are, it is true, finer ridges also present, varying in number and intensity with the age and condition of the weapon. These are the delicate features, often requiring considerable magnification to bring out properly, and easily distorted or destroyed if the bullet be allowed to rub against other solid objects. Whence do they come, and why do they exist?

They exist by reason of the fact that no two material objects either of God's or Man's fabrication are identically the same. The tool which cuts or "rifles" any one groove in a given barrel undergoes wear during the cutting process, and a magnified photograph of the edge of its cutting surface will *not* be the counterpart of a photograph taken of that same surface at the completion of rifling the next groove in the same barrel, any more than will the undulations or "teeth" in the edge of one safety razor blade be exact reproductions as to form and spacing of those in the edge of the next blade produced upon the same machine. It is humanly impossible for them so to be.

The contour of the surface of the edge of the rifling cutter is going to be reflected in the contour of the bottom of the groove cut by it. (The groove is dug out by a scraping motion, many times repeated, just as you would produce one in a smooth wax surface by drawing the edge of your finger nail, broad side on, across it a number of

FIG 3—Instrument for comparing the grooves on two bullets

* It is ordinarily easy to differentiate between them as they appear on projectiles which have issued from arms of different makes, since no two manufacturers employ the same width, depth and angular inclination in their rifling.

LEGAL ASPECTS OF OBSTETRICS *

By HARRY M. GUSMAN, M.D., PHILADELPHIA, PA

IT is needless to say that it would be impossible for me to deal with all phases of this subject in a paper of this nature. However, I shall try to take up the more important ones.

Pregnancy. First, let us consider the legal aspects of pregnancy. In civil law, it often becomes the duty of the physician to appear before court and to testify as to the presence or absence of pregnancy in the woman under question, especially in the following types of cases:

- 1 Those in which the virginity of a woman is to be determined
- 2 Those in which a woman claims she was impregnated and is with child by a man recently dead, thus attempting to establish an heir in a disputed title or estate
- 3 Cases in which pregnancy is claimed as a means of enforcing claims for unrequited love or to establish a claim of financial support
- 4 When pregnancy is advanced as a plea to prevent attendance upon the witnessstand in an important trial by jury
- 5 Those instituted for blackmail
- 6 Divorce cases in which the wife is accused of illegitimate gestation
- 7 Cases in which a woman is convicted of a crime and sentenced to capital punishment, but the woman pleads pregnancy to bar execution until the birth of the child is accomplished

It is therefore, important for the medico-legal expert, or the physician appointed by the court, to be well versed in all phases of the diagnosis of pregnancy.

Before undertaking the examination of a patient for court procedures, it is best for the appointed physician to obtain the patient's signature to a statement that she is submitting to the examination of her own free will. Otherwise, the physician becomes liable to legal action on her part, the woman claiming that he examined her against her will. In cases where a woman refuses to submit to an examination, she should be warned by the physician that such action will expose her to suspicion of unfair dealings and may be used as valuable evidence against her.

Diagnosis of Pregnancy. The diagnosis may be *presumptive*, it may be *probable*, or it may be *certain*.

It is presumptive when the woman having been exposed, legitimately or illegitimately, to the possibility of conception, presents some or all of the subjective signs of pregnancy in addition to a

minor degree of abdominal enlargement. It is probable, if these signs steadily increase in intensity and other signs develop at proper periods. A pregnancy is certain, only when there are present to so-called positive diagnostic signs. These include the fetal heart sounds, fetal movements, Chadwick's sign of vaginal and vulvar discoloration, and the painless intermittent uterine contractions of Braxton Hicks. For convenience, the signs of pregnancy are grouped broadly under two headings, namely:

- 1 Subjective—those that the patient experiences
- 2 Objective—those that the physician detects by examination

In legal work, however, the objective signs only are to be considered of importance, since the woman may voluntarily be deceiving the physician by narrating the classical group of symptoms, or she herself may be deceived, as was remarkably demonstrated to us in several of our clinics in cases of pseudocyesis or phantom pregnancy. Pseudocyesis, with the one exception of abdominal enlargement, is entirely a subjective consciousness. A thorough history of the case with a complete examination will usually bring these facts to light. The woman is usually near the menopause when menstrual suppression or irregularity is common and nervous manifestations are frequently exaggerated. Abdominal examination will show an accumulation of fat and a resonant or tympanitic note over its entire surface, no fetal outlines can be detected. Examination of the vulva reveals characteristic changes of advancing years. To be certain, it is best in these cases, to employ an anesthetic as ether gas, or chloroform, when the abdominal enlargement will disappear and the true condition will become evident.

Furthermore, it must be remembered that the signs to be looked for will naturally vary with the period of pregnancy to which the woman has advanced. Thus one would not expect to find the positive signs until the second trimester has been reached.

Since we decided to depend on the objective signs only, we must rely, during the first trimester, on the following for a diagnosis: the uniform enlargement of the uterus, the mammary changes and the four "soft" signs, namely, the softened cervix, the soft and boggy fundus of the uterus, the softened uterine segment, and the softened and enlarged mammae.

During the second trimester, the positive signs will be developed, and from the fifth month, when the fetal heart sounds can be detected, to the end of pregnancy—no difficulties should be experienced in diagnosing the true condition.

Aside from the question of pregnancy from

* (Read at a meeting of the Undergraduate Obstetric Society Jefferson Medical College, April 21, 1926.)

land and groove markings are destroyed, however, and if the outlines of a single land or groove, but a fraction of an inch long, remain intact, the fine striations within its borders may readily suffice to link the bullet to the arm that fired it, providing the suspect weapon be available. But what if the coroner or pathologist, in removing the projectile, grasps it with the rough jaws of a heavy pair of forceps instead of opening down to it a tract sufficiently large to make its manual removal possible? In so doing, he runs a chance of ruining the case, so far as identification by a study of the projectile is concerned, nearly as completely as though the missile had never been located at all.

Again, he may wish to place upon the bullet some identifying mark, so that he can swear in court that this is actually the one which he removed from the body of the deceased. The smooth cylindrical portion offers a fine location for such a mark but, from our standpoint, the least desirable. The point of choice is the base if it be not of the hollow type and is not unduly distorted. Otherwise let him by all means select the rounded (ogival) area at the tip (point), where it will not overlie and destroy any of the groove markings. Here again he must be careful, as the point often carries upon it the weave pattern of any thick piece of material—such as a coat or vest—through which it has passed. When more than one missile has penetrated a body this pattern may suffice to connect a given bullet with its point of entry, when this is otherwise uncertain. It should always be preserved intact, and defacement of it can readily be avoided if ordinary precautions are taken. See Fig 4.

I have stated that, if a suspect arm be available, it should be possible to determine whether or not this fired the bullet or bullets recovered from the body. The method of making the necessary tests is described at length in a paper recently published in *The Military Surgeon** and need not be repeated here. Suffice it to say that by the use of a specially designed "comparison" microscope

(Fig 3) the images of fatal and test bullets may be superposed, and their linear striae and land-groove measurements studied in detail and at leisure. If similar markings are present on each (indicating passage through the same barrel) they may be readily recognized (Fig 1, b) whereas the absence of such markings is also easily determined (Fig 1, a). Exploded shells are equally valuable for the evidence they offer, and may be linked up to a fatal arm by methods similar to those applied to bullets.

To recapitulate. In shooting cases of whatever nature, bullets should so be removed that their surfaces will receive no scars or abrasions from metal or other instruments. (After death has taken place there is no reason why this cannot be possible. In the event of removal from the living, however, surgical considerations may take precedence.)

2 Identifying marks should, if possible, be placed on the base of the bullet—otherwise on the rounded portion near the point, avoiding in the latter instance any criss-cross markings already present, since these may reveal the texture of the material penetrated before entry into the victim's body.

3 Under no circumstances should any marks be made upon the cylindrical portion of a projectile.

4 Once removed, bullets should be carefully boxed and labelled. Notes should be made as to particulars of time, place, and date of removal, witnesses present, etc., aside from any pertinent medical data.

5 When a particular weapon is suspected of having fired a given bullet, linkage between bullet and arm is readily effected provided the "finger-prints" which the former bears are reasonably well preserved. This holds equally true in the case of exploded shells.

6 If no suspected weapon be available, it is frequently possible, from a study of the fatal bullet alone, to name the make, caliber, and model of weapon from which it issued, and this information in itself may serve to locate the guilty arm.

* Vol 58, No 2 (Feb.), 1926 p 142

a complete examination, including the breasts, the abdominal surface, the genital organs and a microscopic study of the uterine scrapings for decidual cells and chorionic villi

Delivery in the Dead In addition to the diagnostic features which were discussed under the chapter of Pregnancy in the Dead, one would find at autopsy, some characteristic changes in the uterus and in the birth canal. The recently pregnant uterus decomposes rapidly after death, due to the excessive hypertrophy during gestation, so that the uterus will be converted into a putrescent mass long before the other tissues yield. Quite the contrary is true of the unimpregnated uterus, which would be firm and resistant long after the other soft structures have undergone putrefaction.

This would be taken as positive proof of chastity of the woman. If delivery has occurred just prior to her death, and the examination be made within a few days or weeks, the usual lesions in the vagina and cervix will be found, together with perineal and vulvar lacerations and contusions. Some very interesting instances of concealment of birth have been recorded in which advantage has been taken of the phenomenon known as "Coffin Birth." As the term implies, the birth of a child in the coffin between the thighs of its mother, has been attributed to the action of the gases of decomposition which cause the expulsion of the fetus. Thus certain women have placed a dead child in a similar position in the coffin of a woman recently deceased in order to divert suspicion from themselves in cases of infanticide or to avoid the stigma of illegitimacy. An examination of the body of the deceased woman readily discloses the perpetrated fraud.

Unconscious Delivery "Can a woman unconsciously give birth to a child?" Such a question may confront the physician testifying in court in a suit for infanticide. The woman in such a case may claim that the life of the infant was lost, because she was not aware of the fact that parturition was taking place, or she may claim that she mistook a labor pain for a desire to evacuate the bowels and thus dropped the child down a privy or a commode, thus killing the child.

Any one who has seen different women during parturition will agree that it is indeed rare for full time babies to be delivered without the knowledge of the mother, unless she be under the influence of an anesthetic, narcotic, or intoxicating liquor. Especially, must we consider this feat improbable in primipara. Although unconscious delivery is exceedingly rare, we must recognize its possibility during profound sleep, during a state of coma or syncope, in an apoplectic, eclamptic, hysteric, or asphyxiated woman. A woman suffering from

paraplegia might readily give birth without knowing it and, of course if the woman is dying, the delivery would be accomplished either artificially or spontaneously without her conscious volition. Unless the woman is suffering an attack of any one of the above conditions at the time of parturition, she should not be ignorant of what has occurred, immediately after parturition has taken place, but if she denies any knowledge of the affair, her guilt should be assumed, even though she may be blessed with a roomy pelvis and strong expulsive powers. If the woman, being accredited with a normal amount of intellect, claims she was unaware of her condition of pregnancy prior to parturition, she should be suspected of attempting to conceal her crime. Especially is this true if the woman is not married.

Criminal Abortion The courts do not recognize any distinction between the terms abortion, miscarriage, and premature labor. They refer to the expulsion of the products of conception at any time before full term, as miscarriage or abortion.

Of course, we are taught that abortion is the expulsion of the ovum at any time previous to the formation of the placenta which is about the end of the third month. Miscarriage is the discharge of the fetus from the time of formation of the placenta to the time of viability of the child, which is the seventh month. Premature labor is the discharge of the fetus from the time of viability, but before full term. Criminal abortion, as the term implies, is recognized by all courts as a crime. It consists in destroying by any means whatsoever, without just and insufficient cause, the life of an impregnated ovum at any stage of its development. The legal penalty for criminal abortion varies in different states, but all include imprisonment and fines.

When a physician is called in to see a case which is apparently an abortion, it is a safe rule to follow to consider all abortions criminal unless proven to be otherwise. If the physician has sufficient evidence to believe that the case is a criminal abortion, it is best to avoid interference with the uterus until he has gained as much knowledge as possible concerning the case. In the meanwhile he should institute an expectant plan of treatment, and notify the authorities that he has a "suspicious" case under his care. He must not however, betray the name of the patient, since he may become liable to prosecution. A noteworthy example of this occurred in England recently. An obstetrician was called to attend a patient with a miscarriage. There was doubt as to the legitimacy of the pregnancy. Without stating his reasons, the physician advised his family not to meet socially the patient in question. This excited gossip and led to a suit of libel against the physician.

purely a diagnostic angle, many interesting questions may arise in the course of the trial. Thus the court may inquire—"Is it possible for this young girl, presumably too young for gestation to arise, to be pregnant?" Or on the other hand, the woman under question is well beyond the usual age of menopause and again the question is asked, "What is the latest period at which pregnancy has been noted?"

Precocious Pregnancy is the occurrence of gestation at an unusually tender age. One needs only to consult the interesting literature on the subject and he will be amazed, as was the writer, how early in life a female may be impregnated. The youngest age recorded in which pregnancy occurred was eight years. This case was reported by Tidy in the latter part of the nineteenth century.

An allied case is recorded of a seven pound baby being delivered from a mother but eight years and ten months old. Wharton and Stille report an instance of a baby menstruating in her first year and being delivered in her ninth year of a child weighing seven and three quarter pounds. There are many cases reported of girls from eleven to fourteen years of age giving birth to full sized children. Wilkinson records the case of a negro girl giving birth to twins when she was only thirteen years nine months and five days old.

Late Pregnancy Equally interesting as the above, are the cases recorded of late pregnancies. Halles records cases, one occurring at the age of seventy, and another at the age of sixty-three. Reese records the birth of twins in a woman of sixty-four. It is not very uncommon to hear of normal children being born of mothers in their sixth decade of life. This is possible in women in whom the normal menopause is indefinitely postponed, in which case they continue to menstruate, or menstruation may cease and yet ovulation may continue actively and independently of menstruation. In the very limited practical experience of the writer, one female patient whose history he was taking, claimed she was fifty-nine years old and she was still menstruating.

Therefore, it is a safe general rule to consider every female from eight to sixty years of age as either capable of becoming pregnant or capable of conceiving, even when other apparently impossible circumstances, aside from the question of age, may be present. There is a possibility of gestation even where there exists an imperforate or unruptured hymen. Sherwood-Dunn records the case of a woman from whom he removed both ovaries. She subsequently married, he states, and gave birth to a male child.

Impregnation During Unconsciousness "Is it possible for a woman to conceive while she is unconscious?" "How long can a woman be pregnant and yet be unaware of her true condition?" Such

questions may arise and the physician asked to explain.

It must be granted that intercourse during an unconscious state, the result of deep sleep, coma, hysteria, hypnotism, or from the administration of an anesthetic, is quite possible. If the woman be a virgin, the pain and traumatism to the parts, usually associated with the first coitus, should lead her to suspect the occurrence of events, immediately upon restoration to consciousness. If she is not a virgin, it is quite possible for the woman not to realize her true state during the first two or three months. In all events, the continued suppression of menstruation and the development of the pregnancy should lead any woman with ordinary intellect to suspect her true condition. Only in feeble minded women have such cases of unconscious gestation been recorded. In married women who conceive at or subsequent to the menopausal period, it is quite possible for her to ascribe her condition to some pathologic affection as an ovarian cyst or a fibroid, and thus allow gestation, to advance to near term without accurate knowledge on her part.

Diagnosis of Pregnancy in the Dead When an autopsy is done in cases of suspected pregnancy, as for the purpose of identification, the marks of gestation or delivery are to be found in the uterus, lower birth canal, and in the ovary. The investigation should include a microscopic examination of the uterine scrapings for the presence of decidual cells and chorionic villi which are only present in the pregnant or recently pregnant uterus. The finding of an ovum, embryo, fetus or fragments thereof as decidual cells, chorionic debris or bones, would indicate a pregnancy. The earlier the examination is made, the more conclusive would be the proof. If the embryo had advanced beyond the period of ossification before the death of the mother, bones may be recognized several years later. Moles, also if found are positive proof of gestation.

Delivery in the Living In cases where a woman presents a child as heir to a disputed estate, or in cases of feigned birth, or in cases of infanticide, the physician is often called in to determine whether the woman in question has upon her body the marks of a delivery that will correspond in date with the age of the child. Examinations in such cases must be done soon after the delivery has occurred, if any positive evidence is to be obtained. After the lapse of from eight to ten days, it is difficult, if not impossible, to make a positive statement that labor has occurred, especially in multipara. The tissues will have regained their usual condition in that time, as to present only the slight lesions that follow an abortion. In a case of infanticide, the woman could readily claim that her pregnancy terminated in an early abortion, and thus escape the penalty. In all such cases, it is important to make

who make it their business to follow them aren't the ones for successful practice"

Dr Leslie, although not wholly in accord with the impatience of these opinions, nevertheless expressed firmly his faith in the achievements of the practical men

"They go on, poor fellows, studying the symptoms and never taking it in that the life power is at fault I see more and more plainly that we ought to strengthen and balance the whole system, and to aid nature to make a sick man well again It is nature that does it after all, and diseases are oftener effects of illness than causes But the young practitioners must follow the text-books a while until they have had enough experience to open their eyes to observe and have learned to think for themselves I don't know which is worse too much routine, or no study at all I was trying the other day to count up the different treatments of pneumonia that have been in fashion in our day, there must be seven or eight, and I am only afraid the next thing will be a sort of skepticism and contempt of remedies Dr Johnson said long ago that physicians were a class of men who put bodies of which they knew little into bodies of which they knew less, but certainly this isn't the fault of the medicines altogether, you and I know well enough they are often most stupidly used If we blindly follow the medical dictators, as you call them, and spend our treatment on the effects instead of the causes, what success can we expect? We do want more suggestions from the men at work, but I suppose it is the same with every business The practical men are the juries who settle all the theories of the hour, as they meet emergencies day after day"

As for urban practice, he said

"It is astonishing how little some of the city doctors knew, they relied upon each other too much They should all be forced to drive over hill and dale, and be knocked about in a hard country practice for eight or ten years before they went to town"

In regard to the contributions of active physicians to medical literature, he made a significant observation

"We haven't time to do any writing That is why our books amount to so little for the most part The active men, who are really to be depended upon as practitioners, are kept so busy that they are too tired to use the separate gift for writing, even if they possess it, which many do not And the literary doctors the medical scholars, are a different class, who have not had the experience which alone can make their advice reliable I mean of course in practical matters, not anatomy and physiology But we have to work our way, and depend upon ourselves we country doctors, to whom a consultation is more or less a downright of pride Whenever I hear that an old doctor is dead I sigh to think what treasures of wisdom

are lost instead of being added to the general fund That was one advantage of putting the young men with the elder practitioners many valuable suggestions were handed down in that way"

He himself had acted as tutor to the embryo doctor, in the earlier years of his work, but of late had ceased to do so For the present, however, his instruction was concentrated on an aspiring female physician, whom he had adopted as an infant, and who for years had accompanied him on his rounds

"He patiently taught this eager young scholar day by day, and gave her, as fast as he could, the benefit of the wisdom which he had gained through faithful devotion to his business and the persistent study of many years Nan followed step by step, and while becoming more conscious of her own ignorance and of the uncertainties and of the laws of the practice of medicine with every week's study, knew better and better that it is resource, and bravery, and being able to think for one's self, that makes a physician worth anything There must be an instinct that recognizes a disease, and suggests its remedy, as much as an instinct that finds the right notes and harmonies for a composer of music Men and women may learn from others, but there is something needed beside even drill and experience, every student of medicine should be fitted by nature with a power of insight, a gift for his business, for knowing what is the right thing to do, and the right time to do it, must have this God-given power in his own nature of using and discovering the resources of medicine without constant reliance upon the books or the fashion. The great doctor works for the body's health, and tries to keep human beings free from the failures that come from neglect and ignorance, and ready to be the soul's instrument of action and service in this world It is not to keep us from death, it is no superstitious avoidance of the next life, that should call loudest for the physician's skill, but the necessity of teaching and remedying the inferior bodies which have come to us through either our ancestor's foolishness or our own So few people know even what true and complete physical life is, much less anything of the spiritual existence that is already possible, and so few listen to what the best doctors are trying their best to teach While half-alive people think it no wrong to bring into the world human beings with even less vitality than themselves, and take no pains to keep even the simplest laws of health, or to teach their children to do so, just so long there will be plenty of sorrow of an avoidable kind, and thousands of ship-wrecked, and failing, and inadequate, and useless lives in the fullest sense of the word How can those who preach to the soul hope to be heard by those who do not even make the best of their bodies?"

Dr Leslie was hesitant about experimenting with new remedies, and scorned to adopt a treatment simply because it was in vogue at the prevail-

JEWETT'S "COUNTRY DOCTOR"

By LOUIS J BRAGMAN, M.D., SYRACUSE, N. Y.

SARAH ORNE JEWETT was the daughter of a New England physician, Theodore H. Jewett, by whom she was remarkably influenced in her literary career, and upon whose life and character she had greatly drawn for her notable novel, "A Country Doctor." Written in 1884, this story, with the provincial physician as the leading figure, tells in a quiet, pastoral-like fashion the various incidents that take place in the community about the town of Oldfields. The shrewd delineation of the doctor, with the interesting side-remarks pertinent to the medical profession in the late years of the nineteenth century, serve to make the work of distinct historical value.

One is immediately impressed with the sympathetic and warm description of the doctor, as he hastens to the bedside of a dying woman.

"They all listened eagerly for the sound of wheels, but it seemed a long time before Martin Dyer returned with the doctor. He had been met just as he was coming in from the other direction, and the two men had only paused while the tired horse was made comfortable, and a sleepy boy despatched with the medicine for which he had long been waiting. The doctor's housekeeper had besought him to wait long enough to eat the supper which she had kept waiting, but he laughed at her and shook his head gravely, as if he already understood that there should be no delay. When he was fairly inside the Thatcher kitchen, the benefaction of his presence was felt by everyone. It was most touching to see the patient's face lose its worried look, and grow quiet and comfortable as if here were someone on whom she could entirely depend. The doctor's greeting was an every-day cheerful response to the women's welcome, and he stood for a minute warming his hands at the fire as if he had come upon a commonplace errand. There was something singularly self-reliant and composed about him, one felt that he was the wielder of great powers over the enemies, disease and pain, and that his brave hazel eyes showed a rare thoughtfulness and foresight. The rough driving coat which he had thrown off revealed a slender figure with the bowed shoulders of an untiring scholar. His head was finely set and scholarly, and there was that about him which gave certainty, not only of his sagacity and skill, but of his true manhood, his mastery of self. Not only in this farmhouse kitchen, but wherever one might place him, he instinctively took command, while from his great knowledge of human nature he could understand and help many of his patients whose ailments were not wholly physical."

As if to offer an apology (although none were needed) for such a splendid and capable medical man remaining contentedly in a rural community, the author recited a few facts from his early career:

"Dr. Leslie had somewhat unwillingly undertaken the country practice which had grown dearer to him with every year, but there were family reasons why he had decided to stay in Oldfields for a few months at least, and though it was not long before he was left alone, not only by the father and mother whose only child he was, but by his wife and child, he felt less and less inclination to break the old ties and transplant himself to some more prominent position of the medical world. The leisure he often had at certain seasons of the year was spent in the studies which always delighted him, and little by little he gained great repute among his professional brethren. He was a scholar and thinker in other than medical philosophies, and most persons who knew anything of him thought it a pity that he should be burying himself alive, as they were pleased to term his devotion to provincial life."

Dr. Ferris, once his class-mate, had stopped in his wanderings as a naval surgeon long enough to pay his old friend a visit. In his conversation with Dr. Leslie touching the diversity of types of physicians, he remarked:

"It always makes me covet my neighbor's wits when I see you. If I settled myself into a respectable practice I should be obliged to march with the army of doctors who carry a great array of small weapons, and who find out what is the matter with their patients after all sorts of experiments and painstaking analysis, and comparing the results of their thermometers and microscopes with scientific books of reference. After I have done all that, you know, if I have had good luck, I shall come to exactly what you can say before you have been with a sick man five minutes. You have the true gift for doctoring, you need no medical dictator, and whatever you study and whatever comes to you in the way of instruction simply ministers to your intuition. It grows to be a wonderful second-sight in such a man as you. I don't believe you investigate a case and treat it as a botanist does a strange flower, once a month. You know without telling yourself what the matter is, and what the special difference is, and the relative dangers of this case and one apparently just like it across the street, and you could do this before you were out of the hospital. It's all very well for the rest of the men to be proud of their book-learning, but they don't even try to follow nature, as Sydenham did, who followed no man. A man has no right to be a doctor if he doesn't simply make everything bend to his work of getting sick people well, and of trying to remedy the failures of strength that come from misuse or inheritance or ignorance. The anatomists and the pathologists have their place, but we must look to the living to learn the laws of life, not to the dead. The men who make it their business to write the books and the men

REDUCING THE COST OF SYPHILIS IN INDUSTRY

(REPORT OF 176 CASES)

By WILLIAM ALFRED SAWYER, M.D., and BENJAMIN J SLATER, M.D.,
EASTMAN KODAK COMPANY, ROCHESTER, N.Y.

SIR WILLIAM OSLER has said that if physicians know syphilis in all its manifestations, all things clinical will be added to them. Thus inspiring invitation from such a great master should act as a challenge to all physicians working in industry. Industry offers a rich field for the study of syphilis, for it is here that an opportunity is given to study the individual from day to day and from year to year in relation to his daily work. Viewed from the public health point of view there need be no arguments advanced in favor of this type of endeavor. The reasons are altogether too obvious. In the 176 cases, a resume of which is herewith presented, syphilis is represented in a great many of its manifestations from the primary to the tertiary lesion.

During the last three years we have taken bloods for Wasserman reactions, as follows

1923	932
1924	1237
1925	1278
	<hr/>
	3447

Between $3\frac{1}{2}$ and 4 per cent of bloods taken are positive. Usually bloods which are at first reported as faintly suspicious to cholesterin, later become positive.

In the course of taking the blood for this number of Wassermans, a technique was evolved which seemed to have certain merits. The nurse was placed in front of the extended arm so that the patient does not see the withdrawn blood.

If the patient has any objection to the removal of blood it is not done. As a matter of fact such objections are almost never encountered. The Wasserman reaction was obtained in every accident no matter how trivial, and as many as seems practicable are taken in disease conditions. While the number taken in one day is frequently not large, when carried on year after year the total number comes to represent a survey of almost 60 per cent of the older employees.

Even though the total number of blood specimens taken is relatively large, we have had no accidents and there has been practically no complaints directed at this type of service.

Dr W. E. Menninger* in the *American Journal of Syphilis*, Vol. 9, No. 3, July, 1925, has shown that in 72 per cent of his syphilitics there was difficulty in wound healing following operation. Practically all standard books

on surgery recognize that syphilis is an additional hazard in operations.

The following cases illustrate the practicability of discovering syphilis and its application to industry. While it will be noted that many employees claim that their disease came because of some condition connected with the work, there is not an instance where an employee claimed that he contracted the disease from another employee. In other words, in the 176 cases there is no claim on the part of any employee that he was infected by another.

A female employee struck the back of her hand against a machine. This did not yield to ordinary treatment, the pain continued for over one month, and the patient was dissatisfied. Another employee was struck with the handle of a truck in the left groin, it broke down, discharging pus, and there was general enlargement of other nodes besides those struck, the case dragged along for some time without a cure. Another employee fell, striking his knee, six months later he developed soreness, tenderness, and some swelling in the knee, which conditions he traced to the preceding fall, claiming compensation. A woman claimed that a furuncle in the groin was the result of a fall. Three employees complained of back injuries with prolonged residual pain. Nine had infections of the fingers, five of which were almost impossible to heal. Four claimed that their skin was being poisoned by conditions of their work, each had a macular eruption on the forehead and felt that it came from chemicals. There were four others who had leg ulcers, claiming injury by striking against objects. One employee believed that chemicals were causing him to lose his vision in one eye. In two months his vision had dropped from 20-20 to 20-200 in one eye.

In each of these twenty-five cases, the Wasserman was four plus, and anti-syphilitic treatment cleared up the condition. The compensation aspect of the case was forgotten when a cure was effected. What the saving was financially is difficult to say, but we know it must have been great when we consider that the award for one eye is \$4,000. Certainly the protection which has been effected in every case more than compensate for the cost of this service. With this in mind, it would seem that the best way to avoid complications of injuries is to anticipate them.

To those industries which pay for absence because of sickness as well as accident compensation, this work becomes of added inter-

ing moment Thus he protested sternly against "the haphazard way of doctoring, in which the health of the patient was secondary to the promotion of new theories" And he was somewhat put out by the fact that "the young scholar who could write a puzzling technical paper too often outranked the old practitioner who conquered some malignant disorder single-handed, where even the malpractice of the patient and his friends had stood like a lion in the way"

None the less he was not afraid of new ideas, and always held out a welcome hand to those progressive minds of the younger generation As an index of his willingness to cooperate, he instanced the many new publications which he was constantly adding to his subscription list And he was extremely proud of the "long rows of his dear library acquaintances, his Braithwaites and Lancets, and their younger brothers, beside the first new Sydenham Society's books, with their clumsy blot of gilding And he would stand sometimes with his hands behind him and look at the many familiar rows of brown, leather-covered volumes, most of them delightfully worn with his own use and that of the other physicians, whose generous friend and constant instructor he had been through years of sometimes stormy but usually friendly intercourse and association"

After his fair apprentice had made sufficient headway to be reliable, he felt inclined, he said,

to open an office in town, and specialize in heart diseases, "since everybody had a specialty nowadays" The modern conception of *ours* being the age of over-specialization is here revealed as being somewhat out-dated!

One glimpses in the following paragraph a worshipping daughter ennobling a doctor of medicine

"If clergymen knew their congregations as well as physicians do, their sermons would be often more closely related to the parish needs Nobody sees people as they are and finds the chance to help poor humanity as a doctor does The decorations and deceptions of character must fall away before the great realities of pain and death The secrets of many hearts and homes must be told to this confessor, and sadder ailments than the textbooks name are brought to be healed by the beloved physicians Teachers of truth and givers of the laws of life, priests and ministers—all these professions are joined in one with the gift of healing, and are each part of the charge that a good doctor holds in his keeping"

Has the true worth and the grave sense of responsibility fostered in the heart of the ideal physician ever been more accurately epitomized? No doctor, cherishing the love of his profession, can afford to overlook this masterful story by Sarah Orne Jewett

HOW TO GET A DOCTOR AT ANY TIME

The July issue of the Ohio State Medical Journal contains the following editorial

"The City Health Department in Dayton, through Dr A O Peters, health commissioner, has undertaken a publicity campaign to acquaint people 'How to Get a Doctor Any Time,' regardless of the financial status of the patient, or ability to pay a fee

The remedy is as simple as the problem sounds complicated In brief, it is for every family and every adult to establish relations with a physician

In large cities the persons unable to pay have district physicians available Those able to pay, if they have a family doctor, receive prompt attention, for the physician has a sense of responsibility toward the patient

"In the days when everyone had a family physician," a current bulletin from Dayton states, "there was no complaint about the lack of prompt attention Then came the time when the laity caused the abandonment of the old time relationship between doctor and fam-

ily by running promiscuously to different physicians, including specialists, without the guiding advice of one doctor who feels responsible for the conduct of the case This practice has forfeited to the people the old time feeling of responsibility which the family doctor had The new way may be better, it may be that people get better diagnosis and better treatment, but there is no doubt that in fostering this idea of decentralization in professional relationship, much has been lost by the patient in forfeiting the personal interest of the physician which the patient formerly enjoyed

"The few people who still employ a family doctor receive prompt attention even when their own doctor may not be immediately available For these persons, there are always a number of physicians who "swap calls" so that when the regular doctor cannot be reached one of the others is glad to act temporarily It is only the people who have no such relationship with a physician who have trouble getting service"

pensaries, but refer the individual to his own physician, to a specialist, or to a clinic. There is a syphilis register, and a case is followed from year to year. Without this register, and without this follow-up treatment, who can say what these cases would have cost industry in complications if treatment had not been instituted?

It is not our policy to discharge a man who has syphilis. If such were the case, it would soon become impossible to get the Wasserman reaction of anybody. There is the greatest effort at cooperation, and every assistance and encouragement is given the employee to get treatment as quickly and as reasonably as his financial condition will permit. The public clinics in the city have proved a great help in this work.

That the patient frequently does not realize the value of this type of service is shown by the fact that 18 employees quit within three months rather than submit to the follow-up. Six others never reported for work at all. In other words, out of 176 cases, 24 or 13 per cent preferred no treatment at all, and left rather than be reminded that treatment was necessary. The turn-over in syphilis is tremendous under the best of circumstances. One wonders what the future will be in eradicating this disease when such a large percentage will not take treatment at a price which hardly covers the cost of the medicine. Of those discovered, not over 15 per cent had previously received anything like adequate treatment or follow-up.

If, however, all physicians in industry will tackle this problem earnestly, there is little doubt that great progress will be made. The Wasserman reaction will be popularized in the family as well as with the patient. More cases will be taken care of, and may there not grad-

ually develop a changed attitude on the part of employees in reporting it. Constant hammering will bring results. Industrial medicine offers an unusual opportunity to discover the disease, and above all, the follow-up becomes relatively easy when the patient remains in the company's employment.

In those communities in which there are no public clinics and no adequate facilities to adjust charges to the financial condition of the patient, it is the authors' feeling that a clinic could be established in the company at no great expense. The results, it is believed, would pay for any cost which would be attached to this type of service.

SUMMARY

1 It is possible with a proper technique to get many Wasserman reactions in industry with comparative ease.

2 Early treatment of syphilis is the best preventive of complications following accidents, and periods of disability are thus cut down. There is a reduction in sick benefit payments for the same cause.

3 A perfect follow-up system is possible as long as the employee continues his employment.

4 The work has three aspects. It is a protection to the individual, to public health, and to industry.

5 Blood was taken from 347 individuals. Between $3\frac{1}{2}$ and 4 per cent gave positive reactions.

6 Syphilis is costly to industry and the State and the taking of more bloods will help greatly in reducing the incidence of syphilis in the community.

RESPONSIBILITY FOR THE EFFECTS OF SEVERE THYROIDISM

By FRANK H. LAHEY, M.D., BOSTON, MASS.

ONE dealing with toxic goitre in limited numbers is not likely to be impressed with the possible seriousness of the disease, both from the point of view of death and also that of permanent and disabling effects. Where, however, the cases of this condition are seen in large numbers one cannot fail to realize, first that a very definite number of patients reach such extreme straights in this disease that death results before any operative treatment, or for that matter any form of treatment is possible, and too, that even though death does not follow, such degrees of car-

diac crippling may result from the effects of this disease that either life itself is immediately threatened by the decompensation ensuing or the individual is converted by the decompensation, plus thyroidism, into such a state, that the necessary measures undertaken for the relief of this condition are made extremely hazardous.

In proof of the above two statements, as to possible serious outcome in hyperthyroidism, in this clinic during the years 1921-22 and 23 there were more patients with toxic goitre who died before they could be operated upon than died after they

est. Ordinarily there is more money paid out in sick benefits than in accident compensation. It is here that our diagnosis is of assistance to the patient in securing proper treatment, and the Company is saved a great deal in sick benefit.

For example, one employee asked for a three-months' sick leave, planning to change climate. This ordinarily would have been given with pay. The Wasserman reaction was found to be four plus. After receiving treatment at a public clinic the improvement was so marked that a sick leave was no longer thought necessary.

One employee in 1924, for the first six months, lost 517 hours. After treatment in the last six months of the year, he lost 192 hours, and in 1925 he lost 50 hours. Another employee lost 203 hours in 1922, 203 hours in 1923, after treatment in 1924, he lost 12 hours, and in 1925 he lost 30 hours. Without treatment the tendency, of course, would be to lose more and more time every year. The saving in sick benefits is obvious.

Many other illustrations could be given of employees who were absent because of this disease. The list is so long that only classical examples may be cited. The value from the patients' point of view can, of course, not be estimated in terms of dollars and cents. Such benefits must necessarily greatly exceed any financial considerations which enter into a discussion of this series of cases.

Forty-nine who had lost time because of sickness had a Wasserman reaction taken on return to work. This had not been done by the family physician. In every case it was positive. This shows the value of the examination after a period of sickness, also how much may be overlooked by failure to take the Wasserman.

Of the 176 cases, 28 were discovered on preliminary physical examination. Of these, 6 never reported for work. Here is an illustration of the value of physical examinations.

Summarizing, these 176 cases were discovered as follows:

- 30—After an accident
- 49—After illness
- 28—On physical examination
- 69—As the result of other conditions

Clinically, we had one primary lesion of the lip proved by the Wasserman and darkfield examination. We had three cases of secondary, and the remainder were of the latent or tertiary states. One case had gross swelling of the lymphatic cervical chain resembling a sarcoma. It promptly melted away under anti-syphilitic treatment. Two cases had tertiary gummas of the nose. One of these had a curious complex—he persisted in sounding the fire alarm,

as the resulting confusion stimulated his unbalanced imagination. He was also very forgetful. He returned to normal following treatment, and has continued to work since.

From an industrial point of view there is no symptom which is more difficult to handle than syphilitic asthenia. In many of these cases it was very difficult to get these employees to take treatment. Their whole attitude was characterized by a great indifference to everything. Promises made were frequently not kept. One man who had five children would sit by the fire entirely indifferent to the state of his family needs. There is no doubt that the *spirochaeta pallida* takes away the energy of many workmen, and from useful citizens they come to lead a vegetative type of existence which is incompatible with industrial efficiency. The whole picture of a syphilitic asthenia is that of an individual who is entirely insensitive to his own, his family, or industrial needs.

The sexes were divided as follows:

Married males	97
Single males	48
Married females	20
Single females	11

Of the married males, only five could be persuaded to bring their wives for a Wasserman test. Of these five, two were negative and three were positive. Curiously enough, the wives did not take enough interest to want to know if they had the disease, for it is certain that most of them knew that their husbands were under treatment. Of the 11 unmarried women one was married three days after the fourth dose of salvarsan.

Treatment followed the nuptials, and she later gave birth to a healthy child.

One case committed suicide. Four became insane. One died of uraemia following a drunken debauch.

As to previous treatment:

- 37 had had treatment
- 139 had never had treatment

Two had been treated in the English Army, one in Constantinople, another in Buenos Aires, two in Edinburgh, one in Naples, and another in Hamburg, Germany, one was treated early in a public dispensary. Only nine were actually receiving treatment at the time we made the discovery. It is believed that five were hereditary. From the public health point of view, this shows how inadequate the follow-up is in the ordinary case of syphilis.

Each of our employees who is known to have syphilis is now receiving treatment. We do not give such treatment at our dis-

Chairman—WARDNER D. AYER, M.D. Syracuse
Secretary—HENRY R. GEVELIN, M.D. New York
Surgery
Chairman—GEORGE E. BEILBY, M.D. Albany
Secretary—ALBERT G. SWIFT, M.D. Syracuse
Obstetrics and Gynecology
Chairman—HUGH C. McDOWELL, M.D. Buffalo
Secretary—NATHAN P. SEARS, M.D. Syracuse
Pediatrics
Chairman—ARTHUR W. BENSON, M.D. Troy
Vice Chairman—WILLIAM H. DOINELLY, M.D. Brooklyn
Secretary—JOHN AIKMAN, M.D. Rochester
Eye, Ear, Nose and Throat
Chairman—JAMES W. WHITE, M.D. New York
Secretary—WILLIAM A. KRIEGER, M.D. Poughkeepsie
Public Health, Hygiene and Sanitation
Chairman—LEO F. SCHIFF, M.D. Plattsburg
Secretary—WILLIAM L. MUNSON, M.D. Granville
Neurology and Psychiatry
Chairman—HERMAN F. MAY, M.D. Buffalo
Secretary—THOMAS K. DAVIS, M.D. New York
Dermatology
Chairman—HOWARD FOX, M.D. New York
Secretary—EARL D. OSBORNE, M.D. Buffalo
Industrial Medicine
Chairman—BENJAMIN J. SLATER, M.D. Rochester
Secretary—ARTHUR M. DICKINSON, Albany

TRUSTEES

WILLIAM H. ROSS, M.D.
GRANT C. MADILL, M.D.
NATHAN B. VAN ETEN, M.D.
ARTHUR W. BOOTH, M.D.
FREDERICK H. FLAHERTY, M.D., Chairman

Brentwood
Ogdensburg
New York
Elmira
Syracuse

CHAIRMAN, STANDING COMMITTEES

Arrangements—FREDERICK J. SCHNELL, M.D. North Tonawanda
Legislation—HENRY L. K. SHAW, M.D. Albany
Public Health and Medical Education—CHARLES A. GORDON, M.D., Brooklyn
Scientific Work—SAMUEL J. KOPETZKY, M.D. New York
Medical Economics—WILLIAM WARREN BUTT, M.D. Tonawanda

PRESIDENTS DISTRICT BRANCHES

First District—JOHN A. CARD, M.D. Poughkeepsie
Second District—JOSEPH S. THOMAS, M.D. Flushing
Third District—CHARLES P. MCCABE, M.D. Greenville
Fourth District—HORACE M. HICKS, M.D. Amsterdam
Fifth District—CHARLES D. POST, M.D. Syracuse
Sixth District—WILBUR G. FISH, M.D. Ithaca
Seventh District—CLAUDE C. LYTLE, M.D. Geneva
Eighth District—GEORGE W. COTTIS, M.D. Jamestown

THE DIRECTORY

* Copy for the 1926 Medical Directory of New York, New Jersey and Connecticut is now being set by the printer, and if any changes are necessary, they must be made in the very near future.

The new directory will contain the same features as the 1925 edition, but the number of changes is surprisingly great. Over one-third of the physicians listed wish to have changes made in their addresses, or office hours, or telephones, and 500 new names will be added.

The final decision on all data is based on the replies from the doctors themselves. Personal letters were sent to all known doctors in the three states last spring, and follow-up letters have been mailed to those who have not replied. If anyone is not properly listed, the overwhelming probability is that the omission lies with the doctor.

Return your reply card at once.

THE PRACTICE OF PREVENTIVE MEDICINE

Physicians are generally fairly well equipped to recognize fully developed diseases and to treat them after they have been diagnosed. But the stage when a diagnosis is possible has been advanced earlier and earlier in the course of a sickness until now the general character of a disorder may be recognized in its very incipency. A diagnosis implies the immediate establishment of an appropriate line of treatment. Dr Samuel Lambert's definition of diagnosis is peculiarly appropriate: "Diagnosis is a working hypothesis for the application of therapeutics, subject to change without notice on the discovery of further evidence."

Certain combinations of signs and symptoms are associated with each disease. All the signs and symptoms need not be present, but the skilled diagnostician, like the expert mariner, can obtain accurate knowledge from a fleeting glimpse of an abnormal manifestation. It is the detection of the slightly unusual or abnormal that constitutes expertness in the recognition of a disease.

The time to begin specific therapeutics is when a tentative diagnosis is first made. A suspected condition is an invitation to begin treatment immediately, and also to take immediate steps to obtain further evidence regarding the condition, taking a laboratory specimen, making a physical examination, obtaining an accurate history, and all other procedures that may throw light on the condition, but in the meantime measures directed to the suspected condition are to be carried out.

Doctors sometimes assume two opposing attitudes toward early diagnosis and therapeutics. One group, deluded by their own fears, sit still and do nothing except to "wait and see what happens." They fear to take specimens and to make examinations, but they win the praise of their patients by their much solicitude and their protestations of Nature's slowness in "localizing the abscess," or "solidifying the lungs," or in some other way writing the name of the disease in big letters all

over the body. These doctors do not practice the preventive form of medicine.

The opposite attitude is that of the doctor who tells every patient that he is "threatened" with some dire disease. He gives his patient some pills and potions to be taken alternately every half hour, and Lo! in a day or two the disease is averted and the rescued patient is grateful for his deliverance. This sounds like preventive medicine, but it is only its quack imitation.

The practice of real preventive medicine consists in following up the signs and symptoms, be they few or many, evident or obscure. A patient, for example, has one attack of hematuria. The physician who practices preventive medicine will visualize the possible sources of the blood from the prostate to the kidney, and will insist on urine analyses, cystoscopic examinations, and X-ray pictures. Yet it frequently happens that nothing is found and that the signs and symptoms disappear, to the delight of the "wait and see" doctor.

What should a doctor do in a case like this? A patient has a superficial infection of the palms of both hands with some pus, soreness, and throbbing, and then develops a superficial abscess on the skin of his upper arm and a tonsillitis. Is the tonsillitis a part of a mild general septicemia? Are cultures of the blood and throat indicated? Should the administration of serum be seriously considered? All these procedures are demanded as preventive measures.

The practice of preventive medicine by the general practitioner consists largely in diagnosing and treating clinical sickness in its early stage.

The time is now ripe to extend the practice of preventive medicine to include the diagnosis and treatment of disease in its preclinical stage before the patient is aware of the abnormality. This practice constitutes the periodic health examination.

CASE HISTORIES

The written case history in a hospital reflects the impressions of the physician and the methods which he applies to the case. The physician records those conditions which he consciously has in mind during his management of the case.

The absence of a record of essential conditions may mean one of two things—either the doctor forgot to consider the condition, or he did consider it, but found it negative. In the

absence of a record the assumption is that the doctor did not consider the condition at all.

There are no limits to the number of conditions which may be recorded on a history sheet. Great details of family history, repeated analyses of the blood and urine, and detailed examinations of organs remote from the seat of trouble, may confuse rather than aid the diagnostician.

The object of a history is two fold. The immediate object is the diagnosis of the case and the treatment of the patient. The secondary object of a history is to provide facilities for studying a series of cases and comparing one line of treatment with another.

It is to be presumed that the methods practiced in a hospital represent modern standards. They are neither the ultra modern methods of the research worker and specialist, nor the antiquated methods of a decade ago. The methods used in ordinary hospitals are simply those which have been proved useful by modern experience.

Appointment on the visiting staff of a hospital carries the presumption that the doctor will make all the ordinary kinds of examinations that are indicated in the condition that is suspected. As soon as a case is admitted, a tentative diagnosis is made either consciously or unconsciously, and on it is based the next steps of examination and treatment. Every group of symptoms suggests a possible source of trouble and points to a certain organ or region that is involved. An immediate general examination still further fixes the suspicion on a definite part and excludes others from suspicion. Later a detailed examination and study leads to further exactness in diagnosis and treatment.

When a first class diagnostician is confronted with a group of symptoms and signs, he at once forms a mental picture of the probable development of the pathological condition and of its future progress, and the history which he writes will contain the points which he consciously has in mind. If he does not make written records of what he actually sees and hears, he will soon forget even those points which he consciously has had in mind.

A doctor's progress in skill in the practice of medicine is reflected in his histories. If at the end of five years' experience a doctor writes no better histories than before, that doctor is still practicing only the medicine that he knew five years ago. He has not contributed the general

store of medical knowledge or helped his brother physicians to make accurate diagnoses. Every hospital, large or small, can not only assist its staff to practice scientific medicine, but it can also add to the sum of medical knowledge. Take the subject of obstetrics, the leading obstetricians prove the efficiency of their standards of practice by means of accurate records of their cases. Almost the only available records with which they may compare their work are those of other experts who command the facilities of special hospitals. There is a great need that small general hospitals should make their obstetrical records available to the experts. It would be exceedingly instructive if a small rural hospital, staffed by general practitioners, should tabulate its records of 100 or 500 obstetrical cases for comparison with those of the specialists.

Progress in medical practice is measured in two ways. 1, by the records of research institutions and hospitals, 2, by the extent of the adoption of the standards by general practitioners. Items of medical progress originate in centers and spread through the great body of physicians with a speed that is in direct proportion to the closeness of contact of the doctors. The centers are crowded together in research laboratories, they are sprinkled through the hospitals, and often are found scattered among general practitioners. Yet doctors in private practice and serving on the staff of general hospitals have the opportunity to do original work and to contribute to the sum of medical knowledge.

It is not to be expected that all doctors will have the inclination or ability or time to tabulate and summarize the records of cases in a hospital, but it is reasonable to expect that they should write histories in hospitals which provide history clerks and all other facilities for the easy making of complete records.

A physician absorbs knowledge from others in direct proportion to his activity in recording his own observations. The best stimulus to medical progress is activity in making records of one's own cases.

BOOTLEG MILK

The recent disclosures of milk frauds within the Department of Health of New York City suggest the probability of an extension of the system to districts outside of the city. However, there is this difference: there is no need of the payment of graft money in the outlying districts because the system of inspection and control is far inferior to that in New York City. The system in New York City is so efficient that inferior milk will be detected and excluded unless the inspectors are corrupted. On the other hand, in border-

ing counties, where no county-wide system of milk control exists, but where there are over sixty uncoordinated health districts, milk dealers can sell milk of any grade with impunity. The result is that the rural section receives milk which cannot be sold in the city. If a health officer takes action good milk will be sent into his district until the stir blows over.

Milk which cannot conform to the low standards of rural districts and that is on the verge of spoiling or souring, can still be sold to the proprietors of small one-man ice cream

stores where "home made" ice cream is dispensed. The managers of dairy routes sometimes show almost childish ignorance in their frank statements. Some dealers have said that the Grade A pasteurized milk which was too old to sell over the counter was poured into cans and sold to small manufacturers of ice cream. There is no system of inspection of small ice cream makers.

Rockland County has an efficient system of inspection control on a county-wide basis. Samples of milk are taken at frequent intervals and examined in the county laboratory, and the counts are made public records. The Rockland County system is to be recommended to all rural counties.

Local health officers have no facilities for tracing the origin of milk that is imported from up-State or from other states, that duty should be performed by the State authorities. A large dealer who sells milk in several municipalities should file a set of scorings with the State Department of Health where it can be had by the local health officers.

This importation of uninspected milk is a new development that requires intensive study, and the cooperation of all the health forces of a community.

The County Medical Society can collect data, give publicity to the standards of wholesome milk, and advise the officials regarding their

duty, and especially they can support the local health officers and boards of health in controlling milk supplies.

Local health officers can at least make reports regarding milk conditions in their districts, and specific recommendations for improvements. Even if their recommendations are ignored, the fact that they have made written reports and recommendations relieves them of the charge of inaction and unconcern.

Local committees on tuberculosis and public health can carry on a campaign of educating the public regarding local conditions and the methods of remedying them.

The Department of Health of New York State can assist the local health officers in securing information, and can stimulate the activities of those who are inclined to be indifferent.

The Health Department of New York City, which is having troubles of its own with bootleg milkmen, has always been willing to assist the rural health officers in their efforts to control milk supplies.

Bootlegging in milk, like that in other lines, flourishes because the indifference of the people is reflected in the actions of local officials. County medical societies have the opportunity to practice civic medicine by arousing public interest in the problem of the purity of milk supplies.

LOOKING BACKWARD

THIS JOURNAL TWENTY YEARS AGO

The New York State Journal of Medicine for August, 1906, contained an account of a meeting of the Society of Sanitary and Moral Prophylaxis held in the New York Academy of Medicine on April 12, 1906. The meeting was on the subject of the education of the public regarding venereal diseases. The chairman, Dr. Prince A. Morrow, in introducing the subject, said:

"The education of the public in sexual matters constitutes a new departure, and it is first necessary to study the situation thoroughly and determine upon the best means to follow. In the education of the general public we have to encounter and overcome the fact that the general public is indifferent and in certain quarters, actively hostile. Then the ordinary means of communication with the public are not available. The newspapers and magazines, which have been such powerful agencies in the enlightenment of the public in regard to

tuberculosis, are closed to the importance of the work of this society."

Legal measures of prevention were discussed by Arthur N. Taylor, Esq., of New York. He said, "I could suggest an act requiring physicians to immediately report and segregate cases of venereal disease coming to their treatment, as they are required to do with many other contagious diseases, but it requires no vivid imagination to conceive that such an act, if it were enforced, would drive most patients to the "cure yourself" method, thus greatly aggravating the harm it was enacted to lessen."

It is gratifying that this fear has been groundless, and that the accepted rule is that venereal diseases shall be reported along with such diseases as measles and smallpox.

The August, 1906, JOURNAL is valuable as a record of the beginning of the work of preventing venereal diseases.

MEDICAL PROGRESS

Some Medical Aspects of Gastroduodenal Ulcer — Anthony Bassler (*Therapeutic Gazette*, June 15, 1926, 1, 6) states that without doubt the majority of instances of frank hemorrhage from the stomach are other than ulcer cases. They should be considered medical at the start and handled conservatively, by rest of body, mind, and circulation, for which morphine is best. The patient is kept warm, abstains from food for twenty-four hours, then takes acid gelatin water, and after a few days fluid diet like that for ulcer. The stomach is washed with ice-water and one or two drams of adrenalin solution instilled. The final treatment depends upon the cause of the bleeding. The diagnosis of acute perforations in the upper abdomen has changed markedly for the better, few cases will be missed if the condition is kept in mind. In the diagnosis of duodenal ulcer too many men depend upon the Einhorn string test, this the writer has not employed for the past three years. The diagnosis of ulcer by the x-rays alone is not an entirely safe clinical procedure, but there are three deductions from the r-ray diagnosis of ulcer than can often be made. When the x-ray report was that of ulcer and characteristic symptoms were present, ulcer was generally found, if the classical symptoms were present and the x-ray was negative, ulcer was usually found, but if the symptoms were absent and the x-ray diagnosis was ulcer, the r-ray was wrong in more than half of the instances. This means that history and symptoms are the most valuable factors in the diagnosis of this condition. The factor of greatest weight in the history of ulcer is periodicity. A comparison of results by various methods of medical treatment proves that older methods were more generally comfortable and required fewer shifts and daily modifications than those of today. The results of the fatty types of diet do not warrant the weathering of the distress they occasion to the patient. The type of diet—Von Leube, Lenhartz, Sippy, Coleman—employed does not make much difference in the results. The only essential is small quantities of highly nourishing bland foods, frequently repeated for the first three or four weeks while the patient is in bed. The best part of the work is done after the patient leaves his bed, when for the first month he should be back on first principles—milk, eggs, cereals, bread and butter (3,500 calories a day). At the end of each month additions to the diet are made. Alkalies must be administered in quality and kind according to the stomach and

body of the individual patient. Most patients come out of the Sippy treatment with more or less toxemia. Tests of stomach acidity indicate how much alkali is needed. Such tests can be made at any time by using a piece of surgeon's silk, the lower end of which is stained with Congo red and contained in a gelatin capsule, which the patient swallows. Bassler finds that calcium carbonate and magnesium oxide are the best alkalies, and should be continued throughout the six months' dieting. If one medical treatment, well done, does not cure, there is no use trying a second. Ulcers of the fundus, body, and anterior wall do comparatively better on medical treatment than those of the posterior wall and lesser curvature. The larger and more indurated the ulcer is, wherever situated, the wiser is a resort to surgery.

Diagnosis of Peptic Ulcer—Cecil Bull (*Practitioner*, June, 1926, cxvi, 6) declares that gastric and duodenal ulcer can be, and should be, diagnosed accurately and definitely in nine out of ten cases. Pre-operative diagnosis is safer, more accurate, and more economical than exploratory operation and under no circumstances are we ever justified in advising or consenting to an operation on a patient with chronic abdominal symptoms unless a careful diagnosis and localization of the lesion have been made beforehand. The diagnosis is made on the history, the physical examination, and the r-ray examination. Every case of peptic ulcer can be made to exhibit Sippy's five clinical characteristics: (1) pain or discomfort in from one half to four hours after a meal, (2) relief for a similar period by a full meal, (3) relief by an adequate (neutralizing) quantity of alkali, (4) relief by completely emptying the stomach, (5) increase of gastric acidity (qualitatively and quantitatively) during the height of pain. A special characteristic of peptic ulcer is the tendency to remit and relapse. Some abdominal discomfort with peptic ulcer is invariable. Mineral acids excite pain. Sugar and alcohol give temporary relief. In gastric ulcer the facts are there just the same but the time occupied in the sequence of events is shorter. The physical evidence is (1) visible peristalsis, (2) palpable abdominal tumor. In both cases these signs will be confirmed by the r-rays. Local tenderness is by no means diagnostic of ulcer. An r-ray examination is the most important single method of examination. The direct signs of gastric ulcer are (1) niche, (2) accessory pocket

The indirect signs are (1) spastic manifestation—incisura, diffuse gastric spasm, (2) retention from a six-hour meal (a barium meal given six hours before examination), (3) alterations of peristalsis. The direct signs of duodenal ulcer are (1) deformity of the duodenal cap, (2) duodenal diverticulum. The indirect signs are (1) hyperperistalsis, (2) retention from a six hour meal. By these signs Carman obtains accuracy in diagnosis in over 95 per cent of cases of gastric and duodenal ulcer. All the data obtained from the history, the physical examination, and the x-ray examination must agree and fit in the picture before a positive diagnosis of peptic ulcer can be made. For instance a patient with gastric symptoms and deformity of the duodenum, as shown by the x-rays, may or may not have duodenal ulcer, he may have had a duodenal ulcer years ago, which had healed, but left a permanent deformity.

Treatment of Gastric and Duodenal Ulcer—Von Eiselsberg writes that he has treated nearly 1700 cases of peptic ulcer and post-ulcerous stenosis during the past quarter century, with an operative mortality of 7 per cent. This figure does not apply to recent years for in his past series of 449 resections his mortality was but 3 per cent, and he is so confident that this percentage can be reduced progressively that he speaks of it as "3 per cent too many." He begins his article in the *Wiener klinische Wochenschrift* of June 17, 1926, with an attempt to solve the mystery of the etiology of peptic ulcer, but although he cites a number of plausible theories he ends by confessing his total ignorance. He passes hastily over the subject of diagnosis which is now well crystallized. In discussing the roentgen diagnosis he states that the number of his cases of suspected peptic ulcer diagnosed in this manner is now 449 with but 3 per cent of error. He outlines the evolution of the surgical treatment of ulcer, much of which took place under his personal observation. Thus Billroth regarded resection as justifiable only for cancer at first, but later added ulcer stenosis. Then gastroenterostomy was found to do well for the latter and at a later period florid ulcer without stenosis was added. Gradually, however, the pendulum has been swinging away from anastomosis to resection and now the latter is regarded as the indication of choice for both ulcer and stenosis. Resection cures radically a large per cent of cases and without the likelihood of jejunal ulcer while it eliminates the danger of cancer. Naturally there are contraindications. If the general health is wretched, if the ulcer is seated at the cardia, if ulceration has involved the pancreas, and if resection will endanger the common duct, one should perform anastomosis. In

the author's 110 operative fatalities the chief causes of death were peritonitis and intrathoracic sequelæ.

False Gastric Ulcers from Foreign Bodies in the Pylorus—Victor Pauchet, the well-known surgeon, has operated twice on a complete diagnosis of gastric or duodenal ulcer and has found respectively a pin and four sewing needles embedded in the pyloroduodenal mucosa. Despite the simulation of ulcers the lesions found were not of that type, but represented only an inflammatory thickening. The condition was therefore that known to clinicians as "ulcer without ulcer" in which one of several conditions will be found—usually a simple gastritis, or else perigastric adhesions. The dominant symptoms in both cases were pain and hemorrhage. In the first case the diagnosis was duodenal ulcer and the patient, a woman of 25, was found to have swallowed four needles, but had no recollection of the fact, which must have gone back at least four years. Pauchet resected the duodenopylorus and made an anastomosis. The second patient was a woman of 59 with symptoms dating back 30 years. After a diagnosis of gastric ulcer had repeatedly been made Pauchet operated but found a pin in the pyloric mucosa. In the duodenal patient melena had been a prominent symptom.—*Bulletin de l'Académie de Médecine*, May 11, 1926.

Hyperpnea, Migraine, and Epilepsy—What is usually called hyperpnea or polypnea is rapid breathing with forcible inspiration of expiration. The voluntary act is referred to commonly, but there is an hysterical polypnea which is involuntary and which is said to give rise to the same effects. O. Muck, writing on this subject in the *Muenchener medizinische Wochenschrift* of June 11, 1926, does not discuss the entire subject of hyperpnea but only its alleged action in causing migraine in migrainous subjects and epileptic seizures in epileptics. He based his study of migraine on 17 female patients subject to migrainous attacks. In 12 the test was positive and in 5 negative. In all of the positive series the author was able to show that there was at the time a hypertonia of the cerebral arteries, which he recognized by the so-called adrenalin-sound or white line test of the nasal mucosa. When the patients were made to practise hyperpnea it was noted that at the end of two minutes migrainous pain appeared, in some cases accompanied with scintillating scotoma or some of the other symptoms which complicate migraine. This state of the cerebral arteries predisposes to other afflictions, notably tetany and epilepsy, and is spoken of as indicative of convulsibility. The pains

ceased at once when breathing became natural. In the same journal J Lange and E Guttman discuss hyperpnea in its relation to hysteria and epilepsy. O Foerster has described epileptic attacks of this origin as polymorphous and the authors, after analysis of a number of cases, reach the conclusion that the epileptic attacks are not typical, but suggest on the one hand hysteria or hysterio-epilepsy and on the other the affective epilepsy of Bratz.

Eradication of Infected Tooth Sockets—In view of the fact that the filling of root canals has proved a failure, inasmuch as every tooth from which the pulp has been removed is either infected or becomes infected within a short time after, and since the pulling of teeth by the ordinary technique fails to eradicate infection, Alonzo Milton Nodine (*Medical Press and Circular*, May 19, 1926, cxxi, 4,540-41) advocates the surgical removal of infected teeth. He calls attention to estimates showing that at the age of twenty-five, 25 per cent of the human race have septic mouths, at the age of forty, 90 per cent, and at the age of fifty, 100 per cent. Conservative estimates indicate that 10 per cent of all local infections have their source in infected teeth. The surgical method which the author recommends consists in making an incision from the cervical margin toward the apex of the tooth, through the gum parallel with the long axis of the tooth, and midway between the tooth to be removed, and the one either anterior or posterior to it. At times two incisions are desirable, one anterior and one posterior. This section of the gum is elevated with the periosteum of the bone, then the external plate of bone covering the tooth is removed, freeing the root and exposing the apical region, so that infected tissue can be seen and carefully, completely and immediately removed. The wound is cleansed, the rough edges of bone are smoothed, and the gum and periosteum are replaced and sutured in position. The anesthetic used is a 2 per cent borocaine solution, injected either to block the main nerve supply or locally. This method makes possible the complete removal of the tooth and infected tissue without fracture, or the destruction of an unnecessary amount of sound tissue, and guards against pushing roots into the maxillary sinus.

A Critique of Bernard's So-called Laws of the First-Born and of Alternation—Simply stated Bernard's law and its corollary are that "If an hereditary defect is to appear in the children of an affected parent it must inevitably occur in the first-born," and "if the children show the malformation at all, the abnormal and the normal children will alternate."

The latter law is rigorous for the first two children, and more or less rigorous after that. Evidence showing that these laws are contrary to the experience of geneticists and those dealing with large numbers of persons suffering from inheritable diseases is presented by Madge Thurlow Macklin (*Canadian Medical Association Journal*, June, 1926, xvi, 6) who has tabulated the findings concerning 76 families with hereditary disease. The results of the study show that there is no greater tendency for the first child to be abnormal than there is for it to be normal. Of the 76 families, 54 per cent had abnormal and 46 had normal first children. It is shown further that abnormal children in such families may be born subsequent to a normal first child—indeed they are liable to appear in 50 per cent of the cases. There is no greater tendency for the affected to alternate with the normal than would be expected on the basis of chance. All possible arrangements of affected and unaffected appear. Such statements as those of Bernard, based on insufficient evidence, are pernicious, Macklin says, and may work to the detriment of the individual from either the eugenic or the medicolegal aspect.

Blood Counts and Internal Secretion—H Zondek and G Koehler discuss this subject with special reference to anemia, leucemia, and polycythemia. If thyreoidin is given to a sound subject in dosage of 0.1 to 0.3 gm and a blood count taken in half an hour the number of erythrocytes may be found to be increased, at times enormously. This increase may be from half a million to two million, without a proportional increase in hemoglobin, which indicates that the new red cells are immature and relatively poor in coloring matter. This phenomenon is not constant and is much more apt to occur in the summer months. Conversely in a certain percentage of individuals, in place of an increase a diminution of red cells will be found to follow these injections and this form of reaction has thus far been found only in the winter months and in all subjects tested, whether well or ill.

From another angle it has long been known that subjects with endocrine disturbances show anomalies of cell counts. Thus a subject with Graves's disease has a tendency to polglobulia, a myxedematous patient to anemia, and a subject with Addison's disease to eosinophilia. Again subjects with thymus hypoplasia show a lymphocytosis, eunuchoids a polglobulia, and actual eunuchs a mononucleosis. Finally patients with pluriglandular insufficiency show a leucocytosis, sometimes large—up to 20,000. Leucemias also show this kind of formula. A number of hormones, not alone thyroid, can alter both the red and white cell

count, even in minimal doses. One milligram of chemically pure dried bone marrow or spleen can cause almost a shock-like disturbance of the blood picture. Hence from what has been said it is evident that with hormones we can set up a genuine anemia, reduce the red cell surplus in polycythemia, or the white corpuscle excess in leucemia—*Klumsche Wochenschrift*, May 14, 1926

Physique, Temperament, Character, Psychopathy, and Crime—The efforts of Kretschmer, first published in 1921, to find physical types as a basis for temperaments, character any psychoses have provoked much interest among alienists and others. As this doctrine is based on thousands of anthropological measurements it has taken time to verify or oppose it. The *Archiv für Psychiatrie* for April 27, 1926, contains no less than four articles bearing on Kretschmer's work. Hans Gruhle discusses the build of the normal man, basing it on measurements on 118 Heidelbergers taken from the skin clinic and presumably free from psychoses. About half of these did not correspond to any simple type and the others were divided into 24 of the slender or asthenic type, 22 of the athletic build, and but 15 of the compact or chunky build (pyknic). In passing it may be noted that not one of the 118 was a typical Nordic. The large proportion of darkish people, including all of the pyknics, showed a heavy admixture of the Alpine or prehistoric western Slavs with the fair ancient Teutons. There was no trouble in isolating Kretschmer's three basic builds but it is not so simple a matter to connect them with temperaments, character traits, and insanities. The asthenics, although agreeing in physical build, were a motley lot in other respects. K. Kolle studied insanity from Kretschmer's viewpoint but saw only superficial resemblance between the schizoid temperament or character and dementia precox; he quotes Hoffmann as finding that only about half of his dementia precox cases showed a schizoid mental constitution before developing insanity. Kolle concluded that there is no radical distinction in physique between precocious demented and those with periodic insanity. A. Bostroem, in a study of victims of periodic insanity, find that the schizoid mental type corresponds to Scheffler's "Gothic" man, so called to distinguish him from the "Greek" man. H. Von Rohden alone seems inclined toward Kretschmer's views, and finds that most criminals, healthy or insane, are schizoids. There is certainly a resemblance between the psychic constitution of the criminal and the kind of crime he affects.

Ephedrine in Asthma—In an article appearing in the *American Journal of the Medical Sciences* for May, 1926, clxv, 5, William S. Thomas reports that ephedrine, administered by mouth to a series of 20 patients suffering from asthma, gave relief to all but 3. In certain asthmatic patients for whom no means of permanent relief had been found, the drug was used in regularly continued dosage with the result of keeping them free during the period of its administration. The dose employed was usually 50 mg. (about 1-10 grain) to adults, if ineffectual, the dose was increased, if it caused tremor, palpitation or other unpleasant symptoms, it was reduced. Children received doses in proportion to their size and age. The drug was usually given in aqueous solution, in which 1 minim contained 1-250 grain of the drug, in a few cases it was given in capsules for convenience. Relief usually occurs about thirty minutes after the ingestion of the ephedrine and lasts from four to twenty-four hours, much longer than is the case with epinephrine. Ephedrine is an alkaloid, the active principle of a plant, ma huang or *Ephedra vulgaris*, which grows abundantly in China. Its physiological effects resemble closely those of epinephrine and are all comparable with those of stimulation of the sympathetic nerve. Its advantages over epinephrine are that it is effectual when given by mouth, its effects are more prolonged than those of epinephrine, its by-effects, tremor and palpitation, are usually absent. It has the disadvantages that it occasionally fails to relieve symptoms when the other drug does relieve, that its effects are produced less rapidly, and that by-effects are occasionally met with which render its use impracticable.

Arrest of Hemorrhage by Intravenous Injections of Sodium Citrate—M. Renaud after two years of investigation at first hand comes out with the statement that a concentrated solution of this salt will check any kind of hemorrhage. It has been known for some years, as a result of experience in transfusion, that sodium citrate can powerfully modify the blood state and some of its activities suggested that it might prove an excellent hemostatic. This was first demonstrated in the clinic by Ottenberg of New York, in a case of hemophilia, while Neuhoof and Hirschfeld employed it before operating in cases in which excessive hemorrhage was feared. The author first tested the method in the hemorrhages of the cancerous and later in various other types. His solution is as follows: sodium citrate 30 parts, magnesium chloride 10 parts, in distilled water 100 parts. The injection is made very slowly into an arm vein, from 15 to 30 cc., according to the weight of the patient.—*Bulletin de l'Académie de Médecine*, May 11, 1926

LEGAL

By LLOYD PAUL STRYKER, Esq
Counsel, Medical Society of the State of New York

THE DOCTOR AS A CITIZEN

The duty to bear arms in case of national emergency, the obligation to pay taxes, are among the elementary requirements of a citizen. The obligation to cast a ballot at the polls belongs within this category, and yet the extent to which this is ignored has constituted a just cause for deep concern, if not alarm, among our thinking people.

But the duties of an American do not stop there. There is the obligation to be a good citizen, to support our institutions and our laws, to put down usurpation, to watch and to prevent infractions of our liberties, to detect and thwart dangerous and unsound tendencies of government to suggest and to promote just measures of legislation, to nominate and to elect honest men to office who will carry these into effect. These duties, for their full consummation, require strong leadership. Leadership should be assumed by those capable of assuming it. The more favored of our people who have received the inestimable advantages of education should assume the high duty of leadership in our affairs.

There is no class of educated men that has studied harder or has had larger opportunities for sharpening and strengthening the mind upon the whetstone of knowledge than those who compose the medical profession. In no walk of life is more time necessarily consumed in preparing for the life work. It is not strange when the doctor, at the age of twenty-seven or twenty-eight, begins his independent economic life, that he should become absorbed in the problems of his vocation. In our present complicated system this result seems almost inevitable. But the doctor should never forget that first of all he is a citizen. His education and his training, the character he must possess in order to fit himself for his lifework, afford materials for leadership which have too often been neglected. In our vast, growing population, our economic life so largely dominated by

large corporate groups, the individual is indeed waging a battle of self-defense for his very existence. At no time were the responsibilities and the duties of the individual greater than in our day. The diminution of individual influences and importance is a tendency to be regretted and if possible to be stemmed. The importance of the clergyman as a spiritual leader of his community, the leadership of the old-time lawyer, and the honorable and trusted role of the old family doctor have been shrinking.

The doctor, by reason of his character and training and the confidence and trust which he receives from those to whom he ministers, has not only the right to leadership in his community, but it is his duty to assume it and to exercise it for the benefit of his generation. However exacting may be the requirements of his private practice, the importance and necessity of individual diagnosis, care and treatment, he should never forget that by reason of his high calling he is a minister of the public health. Wise and progressive legislation looking to this end should be originated, sponsored and enacted through his influence. Nor does his duty stop there. All things which concern the public welfare, the peace, honor, happiness and progress of our people, should concern him and engage his interest—because he is not only a physician but a citizen. For all these problems he has an equipment of education, character and strength which he should bring to bear.

No one appreciates more keenly or apprehends more clearly the tragic brevity of human life than the physician who is brought constantly in touch with death. A few brief years and it is all over. When it is done and the books are closed and the record is written up, it is not the fortune he has succeeded in acquiring, but what, in the largest sense, he has done for human beings, that will determine his biography.

DIAGNOSIS OF STONE IN URINARY BLADDER AND PROSTATE GLAND ENLARGEMENT

A carpenter about sixty-seven years of age residing in a small up-State village, in his complaint against a surgeon stated that some time prior to May 16th he was suffering from trouble with his urinary organs, the exact nature of which he was unable to determine and he thereupon engaged the defendant as a physician and surgeon to attend and treat the condition. He

charged that the defendant was negligent and careless in his examination and diagnosis, performed the same in a perfunctory manner and failed to locate the exact source of the plaintiff's trouble, which could have been easily determined had the defendant surgeon exercised the proper degree of skill and care, that the surgeon advised the plaintiff that he was suffering from stone in

the bladder and had prostate gland trouble, that it would be necessary to perform two operations to relieve him of his condition, that the patient relying upon the physician's advice, submitted to an operation in the performance of which the defendant made an incision in the patient's abdomen, into the bladder, and that upon examination of the bladder it was found that no stones were present therein, but that the bladder was in a perfectly healthy condition, that the operation required the plaintiff to remain in the hospital for a period of about three weeks, that he was thereafter removed to his home where he was examined by another physician, who informed him that he was not suffering from any bladder or prostate gland trouble, but a slight stricture which could be and was cured by the other physician without any operation. He charged that his true ailment should have been discovered by the defendant and that the operation performed was wholly unnecessary and that by reason thereof he suffered injury and incurred expense which he sought to recover in this action.

From the defendant's history of this case it appeared that the plaintiff was referred by another surgeon to him for examination and treatment, that he first procured from the plaintiff a history of his ailment and the symptoms of which he complained, and after a thorough and exhaustive physical examination he made a diagnosis of an enlargement of the prostate gland and the possible presence of stone in the bladder, that in connection with his examination and diagnosis he caused X-rays to be made of the abdominal region, and particularly of the bladder, procuring interpretations thereof by the roentgenologist. Upon completion of his examination he advised

the plaintiff of his findings and diagnosis and further advised a two-stage operation, the first to be performed upon the bladder and then to operate upon the prostate gland. The patient entered the hospital and was operated upon on May 17th. No stones were found in the bladder, but the same was found to be in an inflamed and diseased condition. The patient continued in the hospital for a period of seventeen days, during which time the defendant prescribed and rendered to him the necessary and proper treatment. At the end of his stay in the hospital the plaintiff requested permission to return to his home in an adjoining village for convalescence in preparation for the second-stage of the operation upon the prostate gland. The defendant thereupon consented to plaintiff's returning to his home and arranged for his return to the hospital in two weeks for the second stage of the operation. The plaintiff, however, never returned for any further treatment or operation by the defendant, but instead instituted this action of alleged malpractice.

On behalf of the defendant, supported by the affidavits of the various physicians and nurses who had attended the plaintiff, a motion was made to change the place of trial to the county in which the defendant resided, on the ground of convenience of witnesses, which motion was granted.

The case came on the calendar several times for trial, at each of which times the plaintiff requested an adjournment of the trial. Finally, when forced to proceed with the trial of the action, the plaintiff withdrew his complaint, thus terminating the action in favor of the defendant.

DELAY IN DIAGNOSIS OF A FRACTURE

A suit was instituted against a private sanitarium or hospital for nervous and mental diseases and a physician who was superintendent of the same. In this action the complaint charged that the sanitarium was a corporation operated for the treatment of persons suffering from nervous diseases and ailments, that the defendant physician was in charge of the institution, that the plaintiff had been received as a patient at said institution suffering from a state of nervousness, that by reason of her condition the defendants owed to her the highest degree of care and caution in order to prevent her from becoming excited or her condition aggravated, that on a certain day a nurse at said institution suddenly and without warning, when the plaintiff was attempting to leave her room, shouted so that the plaintiff became frightened, lost her balance and fell. It was further charged that the defendant physician owed to the plaintiff the duty of an immediate examination to determine the nature of her injuries by reason

of such fall, that both defendants had failed in this respect and that by reason of the fall the plaintiff had sustained a fracture of the left thigh bone, which injury was not discovered by the defendants for a period of several weeks, and that by reason of the delay in diagnosis the fracture was aggravated and the plaintiff necessarily suffered by reason of such delay, causing a shortening of the leg of about three inches and a paralyzed condition of the fractured limb.

The defendant physician, as superintendent of the institution, had at no time personally attended or treated the plaintiff, she being under the care of other physicians at the hospital. It was no act of the defendant, as physician in charge of the hospital, which caused the delay in the discovery of the fracture of the plaintiff's thigh and he was made a party defendant in the action because of his position as physician in charge of the hospital.

The action was dismissed.

GRADUATE EDUCATION

THE COURSE IN MONTGOMERY COUNTY

Editor's Note The Medical Society of Montgomery County has been one of the leading societies in promoting graduate education among its members. When the State Medical Society offered courses to the several county societies the leaders of the Montgomery Coun-

ty Medical Society designed a course that was more intensive than those in other counties—in fact, real postgraduate work was required of those who attended the course. The following report of the course was made by the committee that had it in charge.

CLINICAL LECTURES ON CARDIO-NEPHRITIS, HYPERTENSION, AND DIABETES GIVEN BY HARRIS A. HOUGHTON, M.D., NEW YORK CITY

An intensive course of clinical lectures was given evenings at the Amsterdam City Hospital, by Dr. Harris A. Houghton, of New York City, under the auspices of the Medical Society of the County of Montgomery.

The course was started on March 12, 1926, and one lecture was given each week until eight sessions had been held.

The schedule as announced and carried out was as follows:

Collateral Reading Those expecting to attend the complete course will find it desirable to purchase and read in conjunction therewith the following:

Floyd, Rolfe—"Kidney Disease From the Physician's Viewpoint" Published by James T. Dougherty, No. 427 West 59th Street, New York City.

Allen, Frederick M—"Treatment of Kidney Diseases and High Blood Pressure," Part I. Published by the Physiatrie Institute, Morristown, N. J.

Joslin, Elliott P—"The Treatment of Diabetes Mellitus" Published by Lea & Febiger, Philadelphia, Pa.

DuBois, Eugene F—"Basal Metabolism in Health and Disease" Published by Lea & Febiger, Philadelphia, Pa.

Those attending will find it also desirable to bring with them copies of the current issue of the *Journal of the American Medical Association*, as Dr. Houghton will discuss for a few moments at each session articles which touch upon subjects included within the scope of the course.

The equipment required will be a large blackboard, projection lantern and pointer.

Clinical material required for demonstration will include for the earlier sessions patients having blood pressures of 200 mm. or under. They are usually ambulatory cases, and should

be selected from the outpatient departments or from private practices and from among those who are willing to submit to the treatment required as to diet and possible minor surgical operations. The younger patients yield the best results. Later, there should be presented patients with higher blood pressures, and those presenting frank quantities of albumen in the urine with or without blood pressure or edema.

One or two cases of diabetes and high blood pressure, each or both, on whom it is proposed to do some major surgical operation, are desired to illustrate the metabolic preparation of patients for operation, and to watch the post-operative reactions. Cases suffering from diabetic coma, uremia or eclampsia may be presented at any time during the course.

The several sessions will begin promptly at the appointed time and will last from seventy-five to ninety minutes with an intervening ten minutes for relaxation. Lantern slides showing the results of chemical examination of the blood plasma from normal individuals and from patients suffering from abnormalities under discussion, including properly calculated Van Slyke's coefficients for non-threshold substances and of Ambard's threshold for the threshold substances, will be thrown on the screen. Also, charts indicating the progress of different types of cases under satisfactory dietetic and other treatment will be studied and relationships established. It is proposed also to parallel this kind of didactic instruction with a study of cases furnished by the local physicians. Wherever possible, patients should enter hospitals for a week or ten days for proper diagnosis and especially for their own instruction in diet and other essential details.

The services of a skilled dietician and a laboratory properly equipped for doing chemical examinations of the blood plasma are all but essential. In the absence of this kind of assistance, the lectures will necessarily become didactic rather than objective.

the bladder and had prostate gland trouble, that it would be necessary to perform two operations to relieve him of his condition, that the patient relying upon the physician's advice, submitted to an operation in the performance of which the defendant made an incision in the patient's abdomen, into the bladder, and that upon examination of the bladder it was found that no stones were present therein, but that the bladder was in a perfectly healthy condition, that the operation required the plaintiff to remain in the hospital for a period of about three weeks, that he was thereafter removed to his home where he was examined by another physician, who informed him that he was not suffering from any bladder or prostate gland trouble, but a slight stricture which could be and was cured by the other physician without any operation. He charged that his true ailment should have been discovered by the defendant and that the operation performed was wholly unnecessary and that by reason thereof he suffered injury and incurred expense which he sought to recover in this action.

From the defendant's history of this case it appeared that the plaintiff was referred by another surgeon to him for examination and treatment, that he first procured from the plaintiff a history of his ailment and the symptoms of which he complained, and after a thorough and exhaustive physical examination he made a diagnosis of an enlargement of the prostate gland and the possible presence of stone in the bladder, that in connection with his examination and diagnosis he caused X-rays to be made of the abdominal region, and particularly of the bladder, procuring interpretations thereof by the roentgenologist. Upon completion of his examination he advised

the plaintiff of his findings and diagnosis and further advised a two-stage operation, the first to be performed upon the bladder and then to operate upon the prostate gland. The patient entered the hospital and was operated upon on May 17th. No stones were found in the bladder, but the same was found to be in an inflamed and diseased condition. The patient continued in the hospital for a period of seventeen days, during which time the defendant prescribed and rendered to him the necessary and proper treatment. At the end of his stay in the hospital the plaintiff requested permission to return to his home in an adjoining village for convalescence in preparation for the second-stage of the operation upon the prostate gland. The defendant thereupon consented to plaintiff's returning to his home and arranged for his return to the hospital in two weeks for the second stage of the operation. The plaintiff, however, never returned for any further treatment or operation by the defendant, but instead instituted this action of alleged malpractice.

On behalf of the defendant, supported by the affidavits of the various physicians and nurses who had attended the plaintiff, a motion was made to change the place of trial to the county in which the defendant resided, on the ground of convenience of witnesses, which motion was granted.

The case came on the calendar several times for trial, at each of which times the plaintiff requested an adjournment of the trial. Finally, when forced to proceed with the trial of the action, the plaintiff withdrew his complaint, thus terminating the action in favor of the defendant.

DELAY IN DIAGNOSIS OF A FRACTURE

A suit was instituted against a private sanitarium or hospital for nervous and mental diseases and a physician who was superintendent of the same. In this action the complaint charged that the sanitarium was a corporation operated for the treatment of persons suffering from nervous diseases and ailments, that the defendant physician was in charge of the institution, that the plaintiff had been received as a patient at said institution suffering from a state of nervousness, that by reason of her condition the defendants owed to her the highest degree of care and caution in order to prevent her from becoming excited or her condition aggravated, that on a certain day a nurse at said institution suddenly and without warning, when the plaintiff was attempting to leave her room, shouted so that the plaintiff became frightened, lost her balance and fell. It was further charged that the defendant physician owed to the plaintiff the duty of an immediate examination to determine the nature of her injuries by reason

of such fall, that both defendants had failed in this respect and that by reason of the fall the plaintiff had sustained a fracture of the left thigh bone, which injury was not discovered by the defendants for a period of several weeks, and that by reason of the delay in diagnosis the fracture was aggravated and the plaintiff necessarily suffered by reason of such delay, causing a shortening of the leg of about three inches and a paralyzed condition of the fractured limb.

The defendant physician, as superintendent of the institution, had at no time personally attended or treated the plaintiff, she being under the care of other physicians at the hospital. It was no act of the defendant, as physician in charge of the hospital, which caused the delay in the discovery of the fracture of the plaintiff's thigh and he was made a party defendant in the action because of his position as physician in charge of the hospital.

The action was dismissed.

3 A short resume on the metabolism of calcium and the uses of parathyroid extract (Col-lip)

EIGHTH SESSION

The final session is to be devoted to a short review of the subject matter of the course, the

discussion to follow lines suggested by questions presented in writing at the opening. A final consideration of cases studied during the course will be undertaken, successes and failures noted and prognosis given.

Time is given at the close of each session for those in attendance to ask questions.

REPORT OF THE COMMITTEE

The Post-Graduate Committee of the Montgomery County Medical Society has reported on the course as follows:

"Dr Houghton proved himself to be a good teacher, emphatic in his conclusions and methodical in the grouping of his material which sometimes was quite technical but clarified as the course progressed.

"The attendance during a session when auto travel in the country was impracticable, averaged 28 out of a possible 47.

"Blackboard and lantern slides were used for demonstration. The doctors furnished cases for diagnosis and treatment.

"The laboratory provided the reports on blood chemistry, urines, etc., in advance of the arrival of Dr Houghton. The doctor reviewed the cases each week and checked up treatment and results.

"The effect of diet in some selected cases, illustrated very clearly its importance in the reduction of hypertension. Focal infection (teeth, tonsils, sinuses, etc.) were also recognized in their influence upon metabolism.

"The interest in the clinical session was sustained throughout the course. There have been two opinions regarding the practical value of such a study of metabolism at this particular period of its evolution. On one hand it has been said that those who are accepted as teachers are not in agreement, and that therefore conclusions

are likely to be questionable, premature or misleading and therefore of limited value to the practitioner. On the other hand, it is claimed that there is enough already sufficiently settled to make metabolism and the application of our later knowledge of blood chemistry, of insulin, of uremia, of acidoses, of obesity, of eclampsia, etc., much more comprehensible and applicable to the daily practice of medicine. Whoever has read Joslin and Allen will appreciate this. In this latter opinion, the Medical Society of Montgomery County subscribes. Twenty-eight or more of its members have been given a suggestive and mentally stimulating course that will inspire them for years to come to further study of a topic that has been somewhat hazy and not easy to grasp in ordinary reading. Its reaction upon medical practice will be of positive advantage to the community in which they practice.

"The objection that these subjects touched upon are not yet complete may be applied to all our knowledge. At best, it is relative and tentative. It can never be regarded as finished. A revision of standards will always be necessary to our progress."

Committee,

CHARLES STOVER, *Chairman*

L. H. FINCH

H. M. HICKS

RESOLUTIONS OF THE COUNTY SOCIETY

At a regular meeting of the Medical Society of the County of Montgomery held at Canajoharie, on Thursday evening, June 24th, 1926, the following resolution was introduced by Dr Charles Stover and adopted by the Society:

"Resolved that the Medical Society of the County of Montgomery record its appreciation of the service rendered by the Committee on Public Health and Medical Education in providing this course of education, and recommend the appli-

cation of this principle to other county societies for the advancement of medical progress.

"Be it further resolved, that the thanks of the Society be given to Dr Houghton for his scientific instruction, his genial courtesy at all times, and his success in maintaining sustained interest in the course from first to last.

"Resolved further, that these foregoing resolutions be sent to the Chairman of the State Committee and to Dr Houghton."

WILLIAM R. PIERCE, *M. D., Secretary*

FIRST SESSION

Forty minutes in didactic instruction laying out the program of the course and diagnosis and laying out treatment of cases presented

1 Importance to the family physician of a full understanding of the principles of diagnosis in detecting early nephritic changes and in a comprehension of the alterations in metabolism

2 Thinking in terms of function rather than of pathology, discarding classifications of nephritis based on pathological changes in the kidney

3 Altering our attitude of hopelessness to hopefulness as metabolic changes are better understood and as present day treatment improves life span of nephritics and hypertension patients

4 Interpretation of albuminuria as a manifestation of irritation rather than evidence of nephritis

5 Influence of acute infections on kidney function Applying same principles to chronic lesions

6 Nephric irritations—(a) of chemical origin, (b) of bacterial origin, (c) those originating in food-stuffs, (d) hyperfunction the equivalent of irritation (?)

7 Final effects of prolonged irritation

SECOND SESSION

Forty minutes of didactic instruction Exhibition of slides and charts Clinical diagnosis and suggestions for treatment

1 Definitions "factor of safety", "overload", Ambard's threshold A consideration of non-threshold substances and the calculation of Van Slyke's coefficients

2 Illustrating the affects of prolonged, low grade irritation on kidney capacity Generalized effect of such intoxications on all body cells of which the kidney is only a part, leading to generalized subfunction

3 Progressive retentions in the natural history of Bright's disease as shown by the blood chemical examinations

4 Transference of our allegiance to urinary examinations as a method of examination to chemical examinations of the blood plasma

5 Classification of kidney insufficiencies based on functional limitation and clinical symptoms

6 Two varieties of kidney insufficiencies (a) salt retention, (b) azotemias

7 Two types of salt retention (a) edema, (b) high blood pressure

THIRD SESSION

1 Threshold substances sugar, salt, water, plasma protein (?) Non-threshold substances

sugar, uric acid, urea, creatinin Fundamental differences in the behavior of the kidney to the substance comprised in these two general classes

2 Each substance considered in its normal and pathological aspects

FOURTH SESSION

1 Presentation of charts to illustrate combinations found clinically and considered in theory at the third session

2 Hyperglycemia and concealed diabetes as a complication of high blood pressure

3 High blood pressure as a complication of diabetes Border line cases

4 Effect of pneumonia on salt content of the plasma and the urine, and upon hypertension

5 The low salt diet in high blood pressure and edema, what may be expected of it

FIFTH SESSION

1 General principles of dieting Abandoning the use of the term "calories" for "grams glucose" as a measure of foodstuffs

2 Woodyatt's formulas and their purposes

3 Calculation of diets according to Woodyatt's formulas

4 Physiology of sodium chloride reviewed and its abnormal metabolism Toxicity and irritating effects

5 General principles of the low salt diet and how it may be calculated

SIXTH SESSION (ACIDOSIS)

1 Ionic disassociation, ph or hydrogen ion concentration

2 Van Slyke's theoretical nine areas of acid-base equilibrium

3 The CO₂ of the plasma and its method of determination

4 Lines of defense against acidosis, carbonic acid gas and sodium bicarbonate Interreaction of the sodium phosphate salts

5 Acidosis in clinical practice, diabetic, nephritic, pernicious vomiting, etc

6 Diets of low acid content and other treatment

7 Acid-base content of food stuffs

8 Treatment of diabetic coma

SEVENTH SESSION

1 Metabolic preparation of patients for surgical operation (a) effect of ether administration on corporal metabolism, (b) influence of postoperative acidosis and hyperglycemia in the prevention of healing

2 Uses of insulin in other conditions than diabetes Bringing diabetic patients into glucose-equilibrium without the help of the laboratory

"The multitude of bathing and wading pools about the city for children, he said, had in some cases been shown to be the source of typhoid infections. At the Tompkins Square bathing pool in 1925 seven cases of typhoid were reported."

The New York Sun of August 4th prints a warning about the dangers of public bathing pools, sent out by the Gorgas Memorial Institute. The article says

"Every summer the practice of the eye, ear and nose specialist is materially increased by an influx of patients calling for treatment of diseases contracted in the public swimming pools and bathing resorts

"Acute infections of the ears and sinuses of the nose comprise the majority of these ailments, while infections of the eyes and lids are less frequently met

"How are these diseases contracted and what can be done to prevent them?"

"The use of chemicals in the water and the frequent changing of the water are helpful, but are entirely inadequate in themselves to safeguard the patrons against infection

"A bather with a discharging ear, an infection in the nose or eye, can take one dive and scatter enough germs throughout the pool to infect any number of his fellow bathers. Their ears, eyes and noses become filled with this contaminated water."

The writer then advocates bathing in large bodies of running water where self-purification of the water can take place. There is great need that this warning should be sent out, for the proprietors of bathing establishments at the seaside where pure water is free, build swimming pools for whose contaminated water bathers pay large sums—and as a result bathers also patronize the doctors

SERUM FOR SNAKE VENOM

The newspapers of May 29 and 30 printed accounts of the spectacular transportation of serum for snake venom from the Zoological Garden of New York City to Ithaca for the treatment of a man who had been bitten by a rattlesnake in a laboratory of Cornell University. The patient had intruded into the laboratory and annoyed the caged snakes out of mere curiosity. When his hand began to swell a half-hour after it was bitten, he informed the College authorities, who immediately took steps to secure the curative serum

Snake bites are extremely rare in the United States, but are serious public health problems in India and Brazil. The staff of the Zoological Garden had collected a pint or more of rattlesnake venom and sent it to the Brazilian health authorities for making an antitoxin, and in return they received a small supply of the antitoxin for emergencies, such as that at Cornell

It is gratifying that the serum reached Ithaca in time to save the patient's life and limb

EUTHENICS

The new science of eugenics, which is often mentioned in the daily press, is of special interest to psychiatrists, and to general practitioners who have to deal with nervous per-

sons. The definition of eugenics is well put by James J. Montague in the following verses in the New York Herald-Tribune for August fifth

Eugenics is a science which,
Translated into action,
Will bring to both the poor and rich
Transcendent satisfaction
If this leaves you a bit nonplussed,
We'll make it short and snappy,
And simply state that it is just
The art of being happy

But happiness, of course, depends
On what a man may long for,
Upon the purposes and ends
He happens to be strong for
The hunter's heart expectant turns
To grouse and ducks for shooting,
The burglar naturally yearns
For unrestricted looting

The pug—we mean the pugilist—
Likes life to be exciting
And therefore would, of course, insist,
On quite a bit of fighting
While Senators and Congressmen
Would earnestly endeavor
To talk and talk and talk again,
And keep it up forever

The more this science we peruse
The more it has us guessing,
To let all men do what they choose
Would surely prove depressing
Were statesmen talking all the time
And fighters always scrappy,
And criminals engaged in crime,
We'd none of us be happy!

THE DAILY PRESS

THE PURSUIT OF BEAUTY

The New York Times of March 31st comments editorially on the pursuit of beauty as exemplified by the rapid growth of beauty parlors and says

"There is danger of exaggerating the moral implications of a cosmetics and beauty-parlor industry, with an annual output, as the United States Census would say, approaching half a billion dollars. The age is frivolous, perhaps, but not to the extent that would seem to be indicated by this lavish expenditure on the adornment and refinement of the flesh

"What has happened here is only another instance of specialization and the factory system replacing domestic industry"

"The beauty specialist has become accessible to a population that never could afford the luxury of a boudoir and a capable ladies' maid. Considering the amount of time and energy expended by individual women through the ages in striving for beauty and against the onset of time, the present system probably represents an economic gain. What does count is the newer, and, on the whole, admirable frankness. Formerly the world agreed to overlook the vast secret labor that entered into the maintenance of feminine beauty. Today we resort to the beauty-parlor as openly as to the barber's, and frequently the same person resorts to both

"The doctors have preached hygiene—with a tranquil soul—as the only way to true beauty, and one result has been a tremendous increase

in beauty doctors. Fashions in women's dress have been growing more and more mannish, but the lotion and perfume bills have been going up. The doctors have taught that the only real adornments of youth are those which come from fresh air, exercise, diet, sleep and healthful thoughts. But youth seems to have gone in for artificial reinforcements"

The insinuations of error of judgment on the part of doctors is not supported by facts. Paint and powder and artificial beauty are readily apparent. One cannot help but be impressed with the great preponderance of fairness, clear complexions and well nourished figures of both men and women seen on the streets. No longer is a woman of forty to be considered old. She is young, not because of beauty parlors, but because of the teachings of physicians. Proper diet is now understood as never before, the results of eating green vegetables and drinking milk are seen on every hand. The pale slimness and the flabby fatness of former days have both disappeared from fashion, and in their place have come the natural beauty which is revealed rather than concealed by modern styles of dress.

Beauty parlors will continue to flourish as aids in the maintenance of artificial styles of hair dressing and finger manicuring, but the real beauty of American women and men, too, would continue if beauty parlors were as rare as they were a generation ago.

BATHING IN POLLUTED WATERS

The daily papers of New York City are giving wide publication to the efforts of the Department of Health to control the sanitation of the public beaches and other bathing places. The waters of the East and North Rivers are called public sewers and the beaches at the ocean front are menaced with garbage from the sea, and rubbish left by picnickers. It seems incredible that anyone would leave sharp tin cans and broken bottles on the beaches, and yet these are the subject of several cartoons by the Brooklyn Eagle.

The Herald-Tribune of August 5th says

"Insanitary conditions at beaches near New York City get worse as the season progresses, Dr. Louis I. Harris, Health Commissioner, said yesterday. His latest surveys revealed that Rockaway Beach continued to be strewn

with all kinds of debris and refuse, 'and an occasional dead animal'.

"'From Belle Harbor to Neponset,' the Health Commissioner said, 'the debris has accumulated in similar fashion. From Cross Bay Boulevard it is possible to see littered refuse left by picnickers on the beach.

"This refuse is fly-breeding, and the persons living in the vicinity should attempt to clean up these places until there is devised a systematic method of sanitation."

"Dr. Harris again explained that the municipal bath houses, although floating in the Hudson River, were nevertheless fed by Croton Reservoir water and therefore clean. The East and North Rivers he characterized as 'open sewers,' making it plain that the city authorized no bathing in either stream.

THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA Tenth Decennial Revision. By Authority of the United States Pharmacopoeial Convention, held at Washington, D C., May 11, 1920 Prepared by the Committee of Revision and published by the Board of Trustees. Official from January 1, 1926. Octavo of 626 pages Philadelphia, J B Lippincott Company, 1925

This revision of the Pharmacopoeia became official January 1st last, and differs from former revisions chiefly in scope, as the physicians on the Committee of Revision gave final decision on admission

The present Pharmacopoeia covers nearer than any predecessor to the ideal in having deleted practically all drugs having no definite pharmacologic action—as chloridrus, arnica sumbul, etc., and admitting many long recognized as having definite action—as acetylsalicylic acid, theobromine, quinine and urea hydrochloride, etc The deletions number nearly two hundred

The other notable changes are of pharmaceutical interest chiefly, but show a forward step in the completeness of the presentation. Certainly this revision marks a notable advance from the point of view of the physician
M F DEL.

BAILEY'S TEXT-BOOK OF HISTOLOGY Revised and rewritten by OLIVER S STRONG A.M., Ph.D. and ADOLPH ELWYN, A.M. Seventh Edition, profusely illustrated, William Wood and Co, New York 1925 Price, \$7 00

The fact that Bailey's "Text-book of Histology" as revised and rewritten by Dr Oliver S Strong and Dr Adolph Elwyn, is now in its seventh edition is sufficient evidence of the position it occupies in the mind of the medical public. A criticism of the subject material of this book would be as ridiculous as carrying coals to Newcastle.

A number of the chapters have been completely rewritten and the terminology in some instances has been changed to conform with the most modern style in histology. Many new illustrations have been added. Were it not for a number of errors in spelling which are doubtless due to the proof reader's carelessness and which at times mar the smooth reading, the work of both the authors and publishers leaves very little more to be desired. However, there is no doubt that it can be recommended as one of the most excellent theoretical and practical works in histology that has as yet been published.

MAX LEDERER.

LES ANGINES DE POITRINE. By LOUIS GALLAVARDIN Octavo of 181 pages Paris Masson et Cie., 1925

This book discusses in considerable detail the syndrome of painful cardiopathies. After a preliminary discourse on the difficulties of the subject the "chest pains" as seen in the clinic are discussed under the three headings, organic pains or angina of grave significance, doubtful pains or angina of uncertain significance, and nervous pains or angina of benign significance. The third part of the book is taken up with pathogenic considerations and the fourth part gives studies of twenty cases of the angina syndrome with autopsy reports

E. E C

FACTS ON THE HEART By RICHARD C CABOT M.D., Octavo of 781 pages with 163 illustrations Philadelphia and London W B Saunders Company 1926. Cloth \$7 50

This book is the result of the analysis of 1906 cardiac cases that went to autopsy and were studied by working back into the clinical findings from the post-mortem diagnoses. In this way basic data was uncovered, and

upon these disclosures were built the statistical and clinical facts so thoroughly presented by the author

Cabot does not consider his volume readable as a whole and suggests that the student peruse only the opening and closing chapters and the summaries at the end of each section, and then browse at leisure. We differ with him, insofar as he does not stress the value of the detailed necropsical studies. These with their clinical highlights comprise a splendid portion of the book.

The closing chapter of the book is a masterpiece of condensation. Within 13 pages is summarized an extraordinary amount of knowledge concerning clinical cardiology which should be read and re-read by every physician treating hearts

We must again acknowledge the debt we owe the Boston clinicians for their staunch advocacy of the etiologic classification of cardiac disease.

FRANK BETHEL CROSS

MODERN METHODS OF AMPUTATION By THOMAS G ORR A B M.D., F.A.C.S. Octavo of 117 pages, with 125 illustrations. St. Louis, C V Mosby Company, 1926 Cloth \$3 50

This is a small volume giving a clear statement of the method for each operation in the various types of Amputations having in view the end result of Function following the Amputation. The reasons given for each procedure are logical and are of value to those who are called upon to do this type of surgery

A short chapter on Cinematoplastic Amputations recalls some of the work done in this field of experiment and should stimulate further investigation and reading. A single chapter gives some helpful suggestions on the fitting of artificial limbs and should be of benefit to those who are not located close to the centers where the manufacturers of such devices do the adjusting

E. W S

PLEASURE AND PAIN A Theory of the Energetic Foundation of Feeling By PAUL BOUSFIELD M.R.C.S., L.R.C.P. 12mo of 114 pages New York, E P Dutton and Company, 1926 Cloth, \$2 00

This is a very interesting book in which the author expresses his ideas clearly and briefly. His analyses of pain and pleasure are based upon some very careful observations and his deductions are comprehensive and follow a logical sequence. He shows that pain is not the opposite of pleasure as is the common conception and that both can exist together in the same person without interference.

The chapter dealing with the part played by imagination as a tension producer and reliever is very instructive.

We do not hesitate to recommend this book to those interested in the study of mental processes.

LEWIS J SMITH

SCHISTOSOMIASIS VEL BILHARZIASIS By C. G KAY SHARP M.D., Fellow Royal Institute of Public Health, Chief Medical Officer, Education Department Province of Natal with a foreword by J B CHRISTOPHERSON CMG M.D., F.R.C.P., F.R.C.S. William Wood & Company, New York 1925 Price, \$2 75

This book is the outcome of the personal experience of the author, who is the Chief Medical Officer Natal Education Department, with this infestation, which J B Christopherson in his foreword calls the great endemic disease of the world.

Dr Sharp takes up in order all the clinical, epidemiological, pathological, aspects of the disease, and goes into detail regarding the treatment, both of the individual case, and, what is more important, the mass treatment in schools and villages where they hope to eradicate the disease.

BOOK REVIEWS

MEDICINE MONOGRAPHS

THE THERAPEUTIC USE OF DIGITALIS By G. CANBY ROBINSON. Volume 1. Octavo of 137 pages. Baltimore, Williams and Wilkins Company, 1923. Cloth, \$2.50.

This is an excellent monograph on the subject of this most interesting and valuable drug. Robinson has prepared a splendid account, dealing with the historic, pharmacologic and therapeutic aspects of the fox-glove.

The size of the book, 137 pages, allows ample space for thorough discussion, citation of opinions, and extensive reference lists. It is gratifying to have so much information between the covers of so handy and convenient a volume.

FRANK BETHEL CROSS

VOLUME 2. CYANOSIS By CHRISTEN LUNDSGAARD and DONALD D. VAN SLYKE. Octavo of 80 pages with illustrations. Baltimore, Williams and Wilkins Company, 1923. Cloth, \$2.00.

This little volume is so highly scientific that it probably will be of no practical benefit to the general practitioner. It abounds in many formulae, many paragraphs of French, some of German. It will probably be of immense value to the physiologist.

H. J.

VOLUME 3. EDEMA By LEO LOEB. Octavo of 178 pages. Baltimore, Williams and Wilkins Company, 1923. Cloth, \$3.00.

This book, one of a series on special subjects, gives a comprehensive discussion of the factors concerned in producing edema and variations in these factors in different forms of edema.

Generalized edema, heart, lung and kidney edema and varieties of local edema are considered and experimental work is given considerable space.

Although well worth careful reading and containing reasonable explanations for various forms of edema, the experimental data by different workers is frequently conflicting, so that when one has finished the reading of this monograph he is made to realize that the cause and the relief of edema follow no regulated formulae.

JOSEPH G. TERRENCE.

VOLUME 5. DYSPNOEA By JAMES HOWARD MEANS. Octavo of 108 pages. Baltimore, Williams and Wilkins Company, 1924. Cloth, \$2.25.

This monograph discusses in a most detailed and scientific manner the mechanism and causes for dyspnea. For the ordinary student and practitioner, it is rather too advanced, but for the physiologist it is a storehouse of knowledge and facts.

H. J.

VOLUME 6. INSULIN AND ITS USE IN DIABETES Part 1—Physiology by J. J. R. MACLEOD. Part 2—Clinical Sec-

tion by W. R. CAMPBELL. Octavo of 242 pages. Baltimore, Williams and Wilkins Company, 1925. Cloth, \$4.00.

The authors of this monograph by virtue of their research work and extensive clinical use of Insulin are preeminently well fitted to give to the profession conclusive and authoritative data on the pancreatic hormone.

The work is divided into two sections. The first part is relative to the physiology of Insulin. Here the history of this internal secretion, the methods of preparation of Insulin, experimental deductions in depancreatized dogs and the physiological assay of this preparation are completely discussed and in a manner which readily holds one's attention. The second and greater section is entirely clinical and covers such phases as the early clinical experiments, the cause and methods of control of ketosis, acidosis and coma, the diagnosis of diabetes and its treatment. In successive chapters the methods of determining the dietary requirements of the individual case and the effect of Insulin is propounded in clear and concise language. This section includes a chapter on the general effects of Insulin with particular reference to diabetes in pregnancy and the administration of Insulin in infections. An interesting tabulated analysis of foodstuffs and a number of concise recipes are appended. There is added an exhaustive bibliography covering every phase of the subject.

This work brings the subject up to date. It is a laudable attempt to standardize the treatment of diabetes and present it in a workable form particularly for the general practitioner.

JAMES STEELE.

VOLUME 7. LEAD POISONING By JOSEPH C. AUB, LAWRENCE T. FAIRHILL, A. S. MINOT and PAUL REZNIKOFF. Octavo of 265 pages, with illustrations. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$4.00.

This book contains a report of the study of lead poisoning at Harvard Medical School which work was financed by the National Lead Institute. It is divided into four parts: 1. Chemistry, 2. Pathology, 3. Physiology, 4. Clinical.

It represents an immense amount of work done on this subject in the laboratories at Harvard as well as a very complete study of clinical cases at the Massachusetts General Hospital. Much of the experimental work is original and is a valuable contribution to a subject of such great importance in industrial medicine and public health work. It is to be hoped that it may contribute to the reduction of the hazard in the lead industry of this country which, by the way, is much higher than that of England. This publication is especially timely now because of the great interest manifested by the profession in Blair Bell's lead treatment of cancer.

J. G. W.

METHODS AND PROBLEMS OF MEDICAL EDUCATION (Third Series). Quarto of 242 pages, with illustrations. Published by the Division of Medical Education, The Rockefeller Foundation, 1925.

This volume of descriptions of clinics, laboratories and methods of teaching in different parts of the world is

of great value to those interested in medical education. Most of this volume is devoted to laboratories. The teaching methods at Johns Hopkins and McGill, in the Department of Pathology are of great interest, and are set forth in detail. Laboratories at Cambridge, Harvard, Western Reserve, Groningen, Leiden, Frankfurt, Strasbourg, Peking, and Yale are described.

C. A. G.

THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA Tenth Decennial Revision. By Authority of the United States Pharmacopoeial Convention, held at Washington, D C, May 11, 1920 Prepared by the Committee of Revision and published by the Board of Trustees Official from January 1, 1926 Octavo of 626 pages Philadelphia, J B Lippincott Company, 1925

This revision of the Pharmacopoeia became official January 1st last, and differs from former revisions chiefly in scope, as the physicians on the Committee of Revision gave final decision on admission

The present Pharmacopoeia covers nearer than any predecessor to the ideal in having deleted practically all drugs having no definite pharmacologic action—as chron-drus, arnica, sumbul, etc., and admitting many long recognized as having definite action—as acetylsalicylic acid theobromine, quinine and urea hydrochloride etc. The deletions number nearly two hundred

The other notable changes are of pharmaceutical interest chiefly, but show a forward step in the completeness of the presentation. Certainly this revision marks a notable advance from the point of view of the physician

M F DEL.

BAILEY'S TEXT-BOOK OF HISTOLOGY Revised and re-written by OLIVER S STRONG, A.M, Ph.D and ADOLPH ELWYN, A.M Seventh Edition, profusely illustrated. William Wood and Co, New York, 1925 Price, \$7.00

The fact that Bailey's "Text-book of Histology" as revised and rewritten by Dr Oliver S Strong and Dr Adolph Elwyn, is now in its seventh edition is sufficient evidence of the position it occupies in the mind of the medical public. A criticism of the subject material of this book would be as ridiculous as carrying coals to Newcastle.

A number of the chapters have been completely re-written and the terminology in some instances has been changed to conform with the most modern style in histology Many new illustrations have been added Were it not for a number of errors in spelling which are doubtless due to the proof reader's carelessness and which at times mar the smooth reading, the work of both the authors and publishers leaves very little more to be desired However, there is no doubt that it can be recommended as one of the most excellent theoretical and practical works in histology that has as yet been published

THE ENDOCRINE ORGANS An Introduction to the Study of Internal Secretion. By SIR E. SHARPEY-SCHAFER, LL.D., D.Sc., M.D., F.R.S. Second Edition. Part 2. The Pituitary, The Pineal, The Alimentary Canal, The Pancreas, and the Sex Glands. Octavo of 418 pages, with illustrations. New York, Longmans, Green and Company, 1926. Cloth, \$7.00.

This book is the second part to be published by the author on his studies of the endocrine organs. It covers the pituitary, the pineal, the alimentary canal, the pancreas and the gonads. Of most of the recent works on endocrinology this book is certainly an outstanding accomplishment. At no time is the author carried away by speculative possibilities. Anatomy, physiology, pathology, careful clinical and experimental observations are constantly in the foreground.

The discussion of the pituitary is the most complete of all the recent works, and it is with due thought that the writer emphasizes the significance of histamine in this gland as well as in the other endocrine organs. A brief and valuable description of the history and present status of insulin is given under the study of the pancreas.

One is impressed with the care and thought the author has given his work to bring to light useful information in an unbiased manner out of a haze of experimental and clinical observations. It is a valuable book to the general practitioner who desires concrete information on the present status of the above mentioned internal secretory organs.

JOSEPH S. BENDETSON

POTTER'S COMPEND OF MATERIA MEDICA, THERAPEUTICS AND PRESCRIPTION WRITING. With especial reference to the Physiological Action of Drugs. Based on the Tenth Revision of the U. S. Pharmacopoeia including also many un-official remedies by A. D. Bush. 9th Edition. 12mo of 262 pages. Philadelphia P. Blakiston's Son and Company, 1926. Cloth, \$2.00.

This being the ninth edition of this little compend, which has so long supplied the immediate needs of the student, has been thoroughly revised and conforms to the tenth revision of the United States Pharmacopoeia.

Though brevity of statement is essential in a work of this kind, the essentials are there and for this reason the book is of value to the busy student. F. S.

THE DIAGNOSIS AND TREATMENT OF TUBERCULOSIS OF THE HIP. By G. R. GIRDLESTONE, B.M. (Oxon.), F.R.C.S. Octavo of 94 pages, with illustrations. New York, Oxford University Press, 1925. (Oxford Medical Publications.)

This is an excellent monograph on a specific disease of a particular joint. The author describes in a concise and definite manner his method of diagnosis and treatment of this condition. The text although complete and full is not burdensome. One may not accept all of the author's procedures, and there is no disease in which authorities disagree more than in tuberculosis of joints, still the book is a true contribution to the subject.

We hope the writer will produce other monographs of this character.

J. C. RUSHMORE

A MANUAL OF CLINICAL LABORATORY METHODS. By CLYDE LOTTRIDGE CUMMER, Ph.D., M.D. Second Edition thoroughly revised. Octavo of 547 pages, with illustrations. Philadelphia and New York, Lea and Febiger, 1926. Cloth, \$6.50.

This volume contains numerous additions and on the whole shows a considerable degree of revision of the former edition. A section on cutaneous reactions and a chapter on basal metabolism add materially to enhance the value of this book to the general laboratory worker and the general practitioner. H. M. F.

INDIGESTION What It Is and How To Prevent. ARTHUR L. HOLLAND. 12mo of 130 pages, illustrated. New York, D. Appleton and Company, 1926.

In a thoroughly popular and clear manner the author deals with "Indigestion." The causes, the method of treatment and the means of prevention are discussed. The first chapter is devoted to the anatomy and physiology of the digestive canal and even though somewhat technical is readily understood by the layman.

The discussion of food phobias and food idiosyncrasies are explained in a most lucid manner.

This small book of one hundred and twenty-five pages undoubtedly covers the subject of "Indigestion" completely and interestingly and deserves to be widely read. G.

YOUNG'S PRACTICE OF UROLOGY. Based on a Study of 12,500 Cases. By HUGH H. YOUNG, M.D., and M. DAVIS, M.D. Two octavo volumes, totaling 1,003 pages, with 1,003 illustrations. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$12.00.

It is impossible to give a satisfactory review and estimate of this valuable two-volume work in the space of a few lines. It represents the experience and accomplishments of a master in his chosen field as based upon clinical experience with 12,500 cases. The task involved herein must have been stupendous.

The book is very fully and attractively illustrated and covers every phase of Urology. The chapter on Malformations and Anomalies is most interesting and complete. Eight chapters are devoted to Operative Procedure and Technique. The chapter on Examination of the Urological Patient should be valuable to every clinician. Much of the book is profitably devoted to Urogenital Infections and Neoplasms, also to Neoplasms, as well as to Obstructive Lesions.

The profession owes a deep debt of gratitude to the author for his valued publication. The prominent logical positions held by the many distinguished Urologists who were former residents and students of Dr. Young are an outstanding tribute to the author and his attainments. AUGUSTUS HARRIS

BIRTH CONTROL FACTS AND RESPONSIBILITIES. A Symposium Dealing with this Important Subject from Every Angle. Number of Angles. Edited by ADOLPH MEYER. 12mo of 157 pages. Baltimore, Williams and Wilkins Company, 1925. Cloth, \$3.00.

This booklet contains a series of 12 papers, by a group of authoritative collaborators, presenting the subject of Birth Control from various angles.

The first by Dr. Adolph Meyer may be regarded as a preamble to this new epoch in social evolution—Conscious and Rational Birth Control—"to provide for the future and health of the progeny and not merely the getting of children" is his keynote.

The "Florence Nightingale" of the B. C. movement is a message convincingly and truthfully stated. Here Margaret Sanger does not appear as the trained nurse (her profession) but rather as a modern "Jeanne d'Arc" carrying the torch of light and victory to the world, general and to her sisters in particular. Her conclusions are the result of a painstaking investigation into the problem in an extensive world tour.

All the other contributors are equally sincere and earnest in their portrayal of their carefully collected material bearing on this subject. Lack of space forbids more detailed review.

The economic as well as the conventional point of view is fully discussed embracing the yet unsolved and unsolvable—marriage and divorce—problem in its relation to Birth Control.

It is a compact and authoritative reference that may well be recommended to all students interested in the economic and sociologic problem. HARRY APPEL.

STONE IN URETER

By RALPH L. DOORMASHKIN, M.D., NEW YORK

This paper deals with the significance of stone grooves in the presentation of the kidneys, and on the dilatation of the ureter with rubber bags in the treatment of ureteral calculi, and is based on the study of one hundred and sixty-four cases

IT has been a matter of common observation that a stone may be lodged in a ureter for many weeks and months without seriously hampering kidney drainage or without producing pelvic infection or extensive destructive changes in the kidney marked by hydronephrosis or chronic pyo-nephrosis. The only signs of damage may be evidenced by diminution of the functional activity as determined by elimination of dyes, the presence of an occasional leucocyte in the kidney specimens of urine, and the varying degree of pelvic retention. Renal infections as secondary to obstructing ureteral calculus are not as frequent as one is led to believe from the reports in the literature, while marked hydronephrotic changes with extensive destruction of the renal parenchyma (so called shell kidney) are rare during the first year of the disease.

An attempt was made here to study clinically the relative incidence of kidney changes resulting from calculous obstruction after a lapse of various lengths of time, to explain the mechanical reasons which safeguard the kidney and to establish a basis for conservatism in the management of ureteral stones. The following table was prepared from an analysis of one hundred and sixty-four cases of stone in the ureter, in which complete cystoscopic and roentgen ray investigation was made. A number of these cases were recurrences. The cases dropped out of observation for various reasons were put in a separate group so that a comprehensive survey could be made of the end results of ureteral obstruction in the group which was treated until the stone was removed. It must be stated that in a goodly number of cases kidney drainage was either improved or completely re-established by repeated dilatation of the ureter with indwelling catheters or other cystoscopic manipulations. A number of cases came under observation with marked renal infection which had completely subsided following ureteral catheterization and remained

free of infection although the obstructing stone was not removed for some time.

The figures given below, as already stated, represent the end results of ureteral obstruction, undoubtedly modified by cystoscopic manipulations.

TABLE I

Duration and Location	Infection absent	Mild infection	Acute severe infection	Chronic pyo-nephrosis and extensive hydronephrosis	Stone removed with aid of cystoscope	Operated	Passed out of observation
<i>One day to one month</i>							
Lower 1/3 of ureter	24	9		32	1	9	
Middle 1/3 of ureter	8	2	1	10	1	5	
Upper 1/3 of ureter	8		3	7	4	2	
Bladder and urethra	5			5			
<i>One month to six months</i>							
Lower 1/3 of ureter	23	1		24		4	
Middle 1/3 of ureter	3	3	1	3	4		
Upper 1/3 of ureter	5	1		1	5	1	
Bladder and urethra	5			5			
<i>Six months to twelve months</i>							
Lower 1/3 of ureter	7			6	1	1	
Middle 1/3 of ureter	1				1		
Upper 1/3 of ureter	1	2		1	2		
Bladder and urethra	1			1			
<i>One year and over</i>							
Lower 1/3 of ureter	8		5	10	3		
Middle 1/3 of ureter	2	1	1	2	2	1	
Upper 1/3 of ureter	5	1		3	3	1	
Bladder and urethra	3			3			
TOTAL	109	20	5	6	113	27	24

It has been noted in numerous instances that although the obstruction could not be overcome by the smallest ureteral catheter, urine was obtained through the catheter passed up to the stone, or urine could be actually seen to escape through the ureteral orifice. By injecting indigo carmine, the dye could be seen to escape from the orifice in many of these cases. The obstruc-

FIG. 1.—Ureteral stones, showing different types of linear grooves (arrows)

tion to the catheter is, therefore, not a criterion justifying surgical interference, and the presence of so-called hopelessly impacted stone even for a considerable length of time should, in the absence of renal infection, not be viewed with undue alarm, as we have some mechanism which allows for urinary drainage

Hunner¹ in his work on ureteral strictures has called attention to the fact that in a number of his cases the symptoms were not due to the stone itself but to the associated stricture below the stone, the urine burrowing a groove or a channel on the surface of the calculus, a factor responsible for the maintenance of kidney drainage. Although I may be not entirely in accord with the role played by strictures in formation of the stone as formulated by Hunner, his observation of the stone grooves has led me to the closer scrutiny of the stone specimens removed in my series of cases and helped me to understand many of the clinical phenomena incident to calculous impaction which were hitherto obscure.

In a collection of over one hundred ureteral stone specimens which I was able to procure, removed either by cystoscopic manipulations or by an open operation, definite linear grooves were found in thirty-three cases, which would place their incidence to about 30 per cent. These specimens were demonstrated before a recent meeting of the New York Academy of Medicine. All of them were impacted stones. Some of the stones were channeled deeply, others were more shallow and unless the stone was carefully studied the grooves may have escaped notice.

In one of the cases the channelization was so perfect that a deep tunnel was formed longitudinally through

which a No 5 Charrier olive tip catheter could be passed through. Judging from the history, this stone was lodged just below the uretero-pelvic junction for at least two years. The urine obtained from the kidney was perfectly normal and the elimination of phthalein was good. As several attempts to have this stone come down by intraureteral manipulation failed, it was removed by an open operation and was found to be held on the ureter by a dense fibrinous capsule.

The grooves were found to run either longitudinally, obliquely or transversely across the broader surfaces of the stone, and in a few instances the stone was merely notched at one of its poles or sides. A few of the stones had more than one groove and two specimens showed definite pit formation continuous with the groove, giving the stone a snail-like appearance. I am inclined to believe that the so-called mulberry-like calculi, or those studded with spiculi, having an eaten up, ragged appearance, owe their configuration to the urine burrowing its way to the bladder in an irregular fashion, all over the surfaces of the stone. If these specimens were included in the above group, the percentage of the channeled stones would have been much higher. The so-called floating stones, which act in a ball valve fashion were invariably found to have a smooth surface, and devoid of linear grooves.

The study of the roentgenograms in some of the cases revealed unmistakable evidence pointing to the presence of these grooves. When the groove is very marked and runs transversely, the appearance of the stone shadow may even lead one to the erroneous belief that he is dealing with two stones in the ureter, one placed on the top of the other. The kidney-shaped appearance of some of the ureteral stones on roentgen ray films is due to the grooving in the middle of the stone.

¹Hunner G. L. The Etiology of Ureteral Calculus. *Surg. Gyn. and Obst.* vol 27, p 252, September, 1918.

FIG 2

A—The rubber bag catheter before inflation a, the catheter, b, the rubber bag, c, the filiform tip
B—The rubber bag distended The dotted lines show schematically the eye of the catheter

It is the presence of these grooves that permits drainage and saves the kidney from ultimate destruction. It is the presence of these grooves that explains the fact why a patient may go about for many weeks with a stone in the ureter and yet be subjected to but a few attacks of renal colic. The renal colic is produced by sudden retention of urine in the ureter and the pelvis as result of complete obstruction. This is proved by the fact that emptying of the trapped urine by a ureteral catheter, if one succeeds to pass by the obstruction, is followed instantaneously by complete relief. Why should a stone which remains impacted in exactly the same spot for many weeks and months, as may be proven in numerous instances by roentgenograms, suddenly give rise to agonizing pain after periods of comparative ease? The pains in these cases evidently do not result from the descent of the stone. I venture to explain it by the fact that clogging of the grooves occurs in these cases by mucus, a blood clot or urinary deposits, causing thereby complete obstruction and acute retention of urine above the stone. The spontaneous relief, often observed in these cases is probably due to the forcible washing out of the clogged material by urine, as result of increased hydrostatic intra-ureteral pressure, or in more fortunate cases by the propulsion of the calculus itself.

The comparatively low incidence of severe renal infection or extensive hydronephrotic kidney changes as may be noted from the study of the

above table is undoubtedly due to the maintenance of drainage produced by channelization of the stone, which is nature's protective mechanism. The acute infections have occurred when the stone was suddenly impacted high up in the ureter, the extensive destruction of kidney took place when the stone was allowed to remain in the ureter for years through the failure of recognizing the condition. The table would tend to show that provided the patient is under continuous surveillance, provided one is reasonably certain that waiting will not result in permanent kidney damage and provided the position and the size of the stone are favorable to its removal by cystoscopic means, the stone may be allowed to remain in the ureter for several weeks or months before considering surgical intervention, with the hope that it may be made to come down by cystoscopic manipulations.

It is difficult and perhaps dangerous to set an arbitrary length of time for which a stone may be allowed to remain in the ureter, as each case must be judged according to its own merits. In considering the problems dealing with ureteral stones, the factor of greatest importance is the position of the calculus, that is, the part of the ureter where it is lodged. It is idle to discuss the relative possibilities of operative or non-operative removal of ureteral calculi viewing the ureter as a whole. The various percentages given by different authors can not be interpreted as the true index of what can be done with ureteral

calculi, unless they are accompanied by an explanatory table showing the relative position of the stone. The incidence of operative or non-operative removal of ureteral stones in this series of cases, based upon their groupings at the different levels of the ureter, are widely divergent, as may be gleaned from the following table

TABLE II

Location	Number of cases	Removed by cystoscopic manipulations	Per cent	Operated	Per cent
Lower $\frac{1}{3}$	77	72	93.6%	5	6.4%
